Mr. C. C. PATERSON drew attention to the serious limit of accuracy imposed by not being able to keep the speed constant.

Mr. W. DUDDELL asked if the voltage could not be reduced by means of another quadrature transformer in series with a high resistance instead of being applied direct to the needle.

Prof. C. H. LEES also drew attention to the advisability of reducing the voltage by some means before applying it to the needle.

The AUTHOR, in reply, stated that brush discharges were fatal to accuracy, but could be detected by observing the apparatus in the dark. Non-inductive high resistances for such voltages as 10,000 or more were very expensive and he had avoided their necessity.

A Paper

"On the Behaviour of Incandescent Lime Cathodes,"

by Dr. R. S. WILLOWS and Mr. T. PICTON, was read by Dr. WILLOWS.

Wehnelt has shown that incandescent lime emits a large number of negative ions; if, therefore, hot lime is used as the cathode, a discharge may be obtained in a vacuum tube with P.D.s as low as 30 volts. The alteration with time of these cathodes, under continued use, has been investigated and the following results obtained: (1) When lime is heated on platinum foil, so far from showing fatigue, it actually increases in activity. With P.D.s greater than the saturation voltage this increase may be ninefold. At lower voltages a slow but steady increase up to 100 per cent. has been found. The steady activity falls when the lime is cold; the initial activity may greatly increase. (2) When the lime is heated on nickel foil, if the tube carries a heavy discharge, the current increases to a maximum and then decreases. A greatly increased activity is frequently shown after the lime has been cold for some hours. At the lower voltages the same general variations are shown as with platinum. (3) Great irregularity is frequently shown when the current is first started; at this stage other causes than temperature, such as mechanical vibrations, greatly influence the emission of ions.

Prof. C. H. LEES asked whether the Author had examined the film under the microscope. He wanted to know whether there was any likelihood of the film getting detached from the platinum, and also whether the increase of activity was simply dependent upon the quantity of electricity passed.

Dr. WILLOWS, in reply, stated that he had examined the films with a microscope. The films were very adherent to the platinum. It was impossible to render the platinum free again from the activity with which the lime endowed it. There was no connection between the activity and the quantity of electricity passed. The increase of activity was probably due to the CaO diffusing into the platinum.

A Paper

"On the Formation of Dust Striations by an Electric Spark,"

by Dr. S. MARSH and Mr. W. H. NOTTAGE, was read by Dr. MARSH.

The formation of dust striations by electric sparks has been investigated by many observers. The Paper attempts to explain their formation as being due to hydro-dynamic forces existing between the dust particles while the wave motion is passing over them. The application of this theory to the striations in a Kundts tube has been made by Koenig and Robinson. The wave motion is assumed to be of the spherical progressive type and expressions are obtained from the intervals between consecutive striæ and the distances of the striæ from origin. Measurements were made of striæ formed on a glass plate with vertical central spark. The agreement between theory and experiment is within the experimental error. Experiments with channels of various shapes were made. Illustrations of the various striæ patterns obtained with small obstacles and reflecting surfaces are given, and the use of these as a convenient means of indicating reflecting interference and diffraction of sound waves is pointed out.

Mr. A. CAMPBELL thought the authors' results justified their theory. His own experiments had been made with much slower electric oscillations and with a much less damped wave train than that employed by the authors. In this case he thought it was possible that the distance between the striæ might give the wave length of the oscillations.

Dr. RUSSELL remarked that the formation of striations afforded a very convenient means of determining whether a spark was oscillatory or not. He had found the number per cm. along a long tube was nearly constant, in one case it was 22, while with the same spark 30 striations per cm. were obtained on a glass plate.

Dr. MARSH remarked that the distance between the striæ varied with the amplitude even when the frequency was constant. The striæ interval became slightly smaller along a long tube. Striæ were obtained in progressive wave trains as well as in stationary waves.

A Paper by Prof. E. WILSON and Mr. L. C. BUDD on "PREVIOUS MAGNETIC HISTORY AS AFFECTED BY TEMPERATURE" was taken as read.

TRANSFORMER OIL.

BY ALEXANDER DUCKHAM.

With the steady growth of the electrical supply industry, necessitating the production and use of plant of increasing capacity, particularly of the alternating-current type, more attention has had to be given to the design of commercial transformers. With this increasing size and with competition amongst manufacturers, it has become necessary to obtain the greatest possible value out of the material employed; hence, as the permissible rise of temperature limits the capacity at which an electrical machine can be rated, the cooling of transformers has become of paramount importance. When transformers of only comparatively small capacity were required, air cooling was sufficient, but beyond certain limits this became commercially impossible, to say nothing of the attendant difficulties and of the labour imposed upon the operating staff, and it was necessary to find some more efficient means of dissipating the heat generated and of protecting the transformer. The insulating properties of oils were well known, and notwithstanding their low specific heat and bad conductivity, they appeared to offer the best medium for the purpose. Fairly satisfactory results were obtained, and development upon this line was continued—at first resin oil was used—then mixtures of resin and various mineral oils, and finally mineral oils alone were tried, and as these latter gave the most uniformly satisfactory results it is to this type of oil that our remarks are confined.

In the first place, in order to carry off the greatest amount of heat the circulation must be rapid, and therefore the oil must be quite thin or mobile; but it has, moreover, to work at a comparatively high temperature, and therefore it must not give off appreciable vapour at such temperature. The maintenance of this combination of mobility and high vaporising point, within certain limits, is one of the difficulties which the oil manufacturer has to surmount, because, as is well known, the thin oils have generally low vaporising points, and these latter rise *pari passu* with the increase in body or viscosity. Such evaporation means not only loss of oil, but the vapour may form an explosive or combustible mixture in the transformer or in the chamber in which the transformer is housed.

The oil must, of course, have a fairly high specific resistance or dielectric strength. These two qualities are common to pure hydrocarbon oils in a greater or less degree, and it is with the question

Digitized by Google

possible impurities that we want particularly to deal in this memorandum. The impurities exist in two states—*i.e.*, either in suspension or in solution. Those in the first category can be removed by careful filtration, whilst in the second, moisture is the impurity that interests us most, affecting as it does both the specific resistance and the dielectric strength.

Generally speaking, all oils contain a certain amount of moisture, known as their water of saturation, and if the amount present does not exceed this point of saturation, the oils will remain perfectly bright, but any excess will render the oil cloudy or opaque. However, if the highest tests are to be obtained the oils must be freed even from this water of saturation. This is not a difficult works operation, provided the requisite vacuum pans and desiccating media are available, but to attempt to do this by means of direct heat, as is sometimes done on the job when erecting transformers, is inefficient and dangerous.

The desiccated oil is in a somewhat unstable condition, as it will re-absorb moisture from the atmosphere should opportunity be allowed, although such atmosphere may contain absolutely no moisture in the liquid state, such as rain or mist. For example, a sample of desiccated hydrocarbon oil will on exposure to the atmosphere of an ordinary warm and so-called dried room absorb therefrom water up to a definite point of saturation, such point of saturation being controlled by the temperature, barometric pressure and the state of actual saturation of the atmosphere. It is therefore essential that the oil after desiccation shall at once be filled hot into metal vessels which have been previously dried and which can be hermetically sealed for handling and transit, and that before opening these packages again for use, the transformer and its case shall be carefully warmed and dried, special attention being given to ensure that the coil windings have been freed from moisture, and then the oil may be transferred with all possible expedition. Whilst the transformer is working and is at a temperature above that of the atmosphere, the tendency to absorb moisture is a minimum, but on allowing it to cool if the air has access to the case, absorption of water vapour will take place and trouble may result. For this reason it is desirable to entirely fill the transformer cases with oil and, to as far as possible, seal them, provision being made for expansion and contraction, and this can easily be done by means of a syphon bottle, exposing as little surface as practicable to the atmosphere.

Causes of Deposits or Sludges and of the Thickening of the Oil.

It is recognised that the formation of deposit in a transformer oil, under the conditions of actual use, is an extremely serious matter, and one to be guarded against at all costs. At the very least, such deposit necessitates the cleaning of the transformer coils and the filtration of the oil at regular periods, and this operation in itself is a costly and at the same time inconvenient matter, as it necessitates putting the transformer out of commission for perhaps a day or two. But if precaution be not taken in time local overheating and consequent breakdown may result.

We are much impressed with the importance of this subject and by the absolute lack of knowledge as to the cause of the formation of the deposit, we commenced investigation, and in this research we have been greatly assisted by many of the engineers to the large power companies and by the transformer makers who sent us samples of the oil for examination. The work we have now done forms a complete explanation, and moreover has enabled us to put our oils to such exhaustive tests that we are in a position to guarantee practical immunity where the necessary precautions are observed.

The causes may be enumerated as follows :—

(a) The deposition of atmospheric dust.

(b) The thickening of oil due to evaporation.

(c) The action of the oil on the insulating materials and varnishes of the transformer.

(d) Chemical change in the oil.

(a) *Deposition of Atmospheric Dust.*—This is a cause that is quite easy to overcome mechanically by taking care that both the transformer and its case are perfectly clean before the oil is put in, and that there is no free circulation of air over the oil when the transformer is in use. The reason why these floating particles adhere to the windings is well understood by engineers to be due to electro-static attraction, but this force is not always credited with being as powerful as it appears to be in practice, although, of course, floating particles carried by the upward current of the oil in circulation (which, of course, is greatest near the windings) do not require any special force to draw them against such current and through the oil, but once in contact with the coils they appear to adhere permanently.

(b) *Thickening due to Evaporation.*—The darkening of the oil is, no doubt, caused by the temperature at which it is constantly maintained during the working of the transformer. This change of colour is observable to a greater or less degree with all oils and gives the impression that the oil has become thicker and more viscous, it being ascribed to the evaporation of the lighter constituents; this, however, is the case to only a very small extent, for on redistillation of a good quality oil the lighter fractions show very little variation from the proportion in which they were present in the original oil, and the change is, probably, largely influenced by the factors mentioned in paragraph (*d*).

(c) *Action of the Oil on Insulating Materials and Varnishes.*—That there is sometimes an action between the insulating oil and the varnishes used in the transformer was clearly illustrated some few years ago, when we were consulted by a large user as to the formation of deposit which he had attributed to the oil, as, in his opinion, this oil contained paraffin wax in solution, and he thought this wax was gradually deposited as a sludge. It was, however, clear to us that if the oil was fluid and free from deposit when cold, there was no chance at all of paraffin wax being deposited when the transformer was in commission and the oil comparatively hot.

The chemical examination of the deposit showed no sign of paraffin wax, but it was found to consist largely of saponifiable matter, in which were identified lead and manganese soaps—*i.e.*, combinations of lead and manganese with fatty acids. It was easy, by chemical analysis, to establish that the deposit had such a composition, but it was difficult to account for the presence, not only of the fatty acid, but still more so of the lead and manganese. We naturally suspected that they were introduced in some way with the transformer, and discussing the matter with a manufacturer, the insulating materials were suggested. He subsequently submitted to us, amongst other materials for analysis, some sheets of flexible micanite, the composition of which material is well known, and it was found that when immersed in hot transformer oils the sheets to a large extent lost their cohesion, and on separating the flakes of mica it was seen that in certain places the varnish had been washed out by the oil, especially in those places where it had not dried to a solid state, whilst those portions of the varnish which were hard and dry were little, if at all, affected.

It is a matter of common knowledge that in the manufacture of varnishes certain metals—or, rather, their oxides—are used in the form of so called "driers," because they have the unexplained property of rendering more rapid the assimilation of oxygen by the varnish, thus helping the drying or setting. A portion of the fatty acid formed in the deposit resembled those of the linoleic series, that is, such as are found in linseed oil, which oil is commonly used in the manufacture of insulating varnishes.

We have lately found that saponifiable deposits contain other substances answering to some of the tests of a fatty acid, and these will be dealt with in the next paragraph. Fatty acids, moreover, are very apt to attack lead, and the transformer cases from which lead containing deposit has been removed have been made of corrugated sheet iron, leaded in to a cast-iron base. The results which were obtained by us in this case were submitted to the engineer, who had first propounded to us the theory that the deposit consisted of paraffin wax, and he, in his turn, submitted the details of our investigation to certain well-known independent chemists, who went into the matter, and at the end of about 12 months a report was received from these gentlemen in all respects confirming our work.

The transformer makers are able to secure immunity from this form of sludge by discontinuing the use of soluble and insufficiently dried varnishes.

(d) *Chemical Changes in the Oil.*—It is under this heading that we find the explanation of the formation of the greater part of the sludges and deposits that have in the past been the cause of so much trouble. In spite of the fact that mineral oils have been looked upon as stable articles and non-saponifiable and non-oxidisable, yet, in view of the results of the research work we have carried out, we must now consider this to be a merely comparative statement, and that under the conditions appertaining to a transformer, oxidation and consequent formation of saponifiable products and of the other oxygen compounds undoubtedly does occur.

In the first place there is a constant and fairly high temperature; secondly, there is usually a space above the oil where the cables are attached to the terminals and where air can circulate, and it is well known that the presence of ozone and oxides of nitrogen is often detected here.

Now, from experiments we have conducted, we have found that mineral oils in varying degrees, when exposed to heat, and in contact with oxygen, not only rapidly darken and thicken, but do actually throw out a solid deposit in the form of an amorphous brown powder, and the action is more rapid with oxgyen than it is with air, and still more rapid with ozone. These are the agents which we have to com-

Digitized by Google

bat in a transformer, and more especially as the electrostatic attraction insures any solid matter depositing on the windings. This discovery is of the utmost importance to transformer users, and would at once suggest tests to which their oil should be submitted before selection. There are some oils that are affected to a very much less extent than others, and by the careful selection of crudes from which the transformer oils are to be distilled, and by their subsequent suitable refining, one can guarantee practical immunity from this sludge.

We are still conducting our research on the exact composition of this deposit, and on the saponifiable oil which is simultaneously formed.

ON SHOCK EXCITATION WITH QUENCHING TUBES.*

BY M. WIEN.

The author has already, in a preliminary note in the "Physikalische Zeitschrift," described a new form of shock excitation, using longer spark-gaps, in which, for the purpose of obtaining a better quenching effect, Geissler tubes were inserted in the exciting circuit, in addition to the spark-gap proper.

To enable others to repeat these experiments the author now gives an account of his experiences with such quenching tubes, although the research is by no means completed.

The first experiments relate to ordinary shock excitation with longer spark-gaps, no quenching tube being used. The arrangement employed is shown in Fig. 1, which is self-explanatory. The coil used, with mercury interrupter, gave 7 to 8 sparks per second. The exciting circuit I. comprised two condensers with compressed gas as dielectric, capacity $0{\cdot}86 \times 10^{-3}$ mfd., and an inductance of 35,000 to 40,000 cm. The oscillatory circuit II. contained two similar condensers of the same capacity, an inductance of 39,500 cm., a hot-wire ammeter and an additional resistance, R_2, of manganin wire immersed in oil. The measuring circuit III., which was only used as control, gave indications by thermo-element and galvanometer.

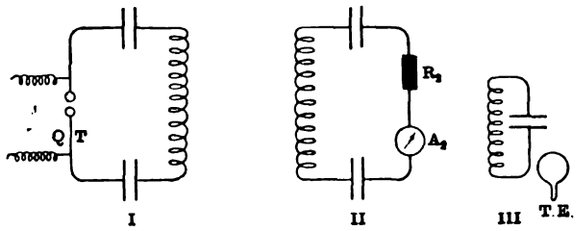

Fig. 1.

With this arrangement, and using zinc electrodes 1 cm. apart, the ammeter showed 0·9 ampere in the oscillating circuit, with close coupling. On diminishing the coupling and simultaneously regulating the tuning a point was eventually reached where the sound of the spark suddenly changed, the ammeter reading rose to 1·3 ampere, and from the shape of the resonance curve obtained with the measuring circuit it was clear that shock excitation was taking place. The degree of coupling at which this effect set in and the value of the current depend, under otherwise similar conditions, very much upon the metal of the electrodes. From the author's experiments it appears that silver cylinders are the best, magnesium the worst. With silver and other metals the spark-gap had to be constantly kept illuminated by an arc lamp for regular sparks to be obtained, but with magnesium this was unnecessary. With silver the critical coupling was sharply defined, a small change causing re-ignitions or complete extinction. With magnesium, on the other hand, the critical coupling is much looser, the change-over ill-defined, while the current maximum scarcely appears. The following table shows the difference in the intensity of the oscillations excited. F is the length of spark-gap in centimetres, A_2 the R.M.S. current in the oscillating circuit. The resistance R_2 had the value 0·75 ohm.

F.	Magnesium electrodes.	Silver electrodes.
0·5	0·46 amperes	0·83 amperes
1·0	0·90 ,,	1·42 ,,
1·5	1·35 ,,	1·75 ,,
2·0	1·75 ,,	2·05 ,,

The difference in the current in the two cases is especially noticeable at the smaller spark lengths.

This form of shock excitation has several defects. The efficiency is, as will be seen later, at high voltages rather small, even with silver, the tuning is difficult and inconvenient owing to the loose coupling, while the shock excitation is no longer pure, since the time taken by the current in the oscillating circuit to reach its maximum is relatively long as compared with its dying away. These defects can be overcome to a certain extent by the employment of multiple gaps and enclosure of the gap in hydrogen, but it can be more simply and satisfactorily effected by the introduction of quenching tubes.

Shock Excitation with Quenching Tubes.—If in the above arrangement a suitable Geissler tube is inserted at the point QT, close to the spark-gap, the quenching effect is greatly improved; the coupling can be made much tighter, and the efficiency rises. The properties of different kinds of quenching tubes will be referred to later on, the following dealing only in general with the mode of action of such tubes.

Resonance Curve of the Uncoupled Exciting Circuit with Quenching Tube.—The insertion of a Geissler tube in an uncoupled condenser circuit has a strong influence on the mode of oscillation; the damping is greatly increased and at the same time the curve is shifted to the right (direction of increased capacity); the wave-length is hence increased. Both these effects increase with decrease in spark potential, but the shift in the resonance curve is much greater in the case of the tube with silver electrodes than with magnesium electrodes. For silver, for a spark-gap of 0·5 cm. the logarithmic decrement is 0·8, and the maximum of the resonance curve is shifted about 12 per cent.; for magnesium and the same spark-length the logarithmic decrement is 0·35 and the increase of wave length only about 2 per cent.

A resonance curve taken of the oscillatory circuit coupled to the exciting circuit shows that, as above remarked, after insertion of the

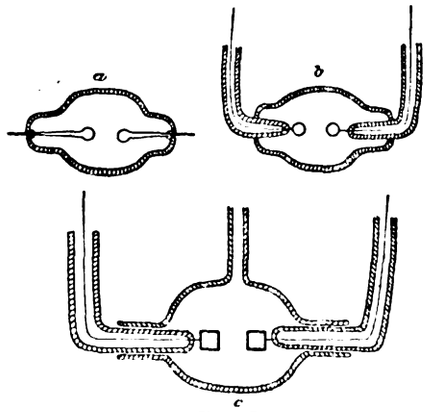

Fig. 2.

quenching tube a pure shock-excitation is obtained, even with a much tighter coupling. If the critical point is passed in making the coupling exceedingly close, the resonance curve does not show the usual two-humped curve of the coupling waves as is obtained when no quenching tube is used, but instead there is a curve with a single though much blunter and smaller, maximum, which corresponds to a sort of incomplete shock excitation. This depends manifestly upon the strong quenching effect of the tube; the re-ignition takes place irregularly—sometimes there is only one—and the spark dies out; the second minimum, or re-ignition occurs twice and the spark dies out at the third minimum, as has been shown by Rau.* The author has only seldom succeeded in securing such regularity of discharge that during a quarter of an hour all the sparks, without exception, have been regularly quenched. It is, however, fairly easy to arrive at a condition where re-ignition occurs in only about 1 or 2 per cent. of the sparks, which is of no practical importance in applications of the method. In all cases where the number of re-ignitions exceeded 20 to 30 sparks—which would be likely to cause trouble in measurements—the author has added a sign to indicate that the conditions were irregular.

Investigation of the Working of Quenching Tubes.—Since the quenching takes place in the immediate neighbourhood of the electrodes the shape of the tube has little influence. The simple wide tubes shown in Fig. 2 (*a*) have proved suitable for general use. Another form which enables cooling means to be applied to the whole tube, is shown in (*b*) of Fig. 2, the tube being cooled by immersion in oil. Yet another form, with the electrode tubes ground in (*c* of Fig. 2), enabling the latter to be changed, has also been used.

In the preparation of a quenching tube it is important to see that

* Translation, somewhat abbreviated, from the "Jahrbuch der Drahtlosen Telegraphie."

* "Jahrbuch der Drahtlosen Telegraphie," IV., p. 52, 1910.

Digitized by Google

the interior of the tube is clean and without the least trace of grease. The working on first being evacuated is not regular, but it soon improves with use; the tube as a rule then remains usable for quite a time—often for months—until it is finally destroyed.

Influence of the Coupling.—On diminishing the coupling between the exciting and the oscillatory circuits, from the critical value downwards, the current in the latter circuit only decreases very slowly. In tubes with aluminium, silver and copper electrodes the coupling could be made three times weaker (2 to 3 per cent.) than the critical value (8 to 10 per cent.) without the current falling much more than 20 per cent. from the maximum value.

Influence of Pressure.—Pressures ranging between 0·015 mm. and 30 mm. of mercury were tried and it was found that only at the lower pressures did the quenching effect become irregular; the best pressure lies between 0·1 and 1 mm. The nature of the gas employed has little influence; hydrogen gives, however, a slightly better quenching than the other gases (air, carbon dioxide).

Influence of the Electrode Metal.—The metal of which the electrodes are made has a considerably greater influence on the results. Small cylinders (1 cm. in diameter and 1 cm. long) of different metals were used in the experimental tube described (Fig. 2, *c*), and it was found that silver gave the best quenching, magnesium the worst; aluminium comes between the two, and has a very marked quenching effect, although it cannot be used at such high potentials. As regards size, with larger electrodes (20 sq. cm.) the same degree of quenching could only be reached with lower gas pressures; while the R.M.S. current in the oscillatory circuit is larger with the smaller electrodes (5 sq. cm. and 1 sq. cm.). On the other hand, with high potentials and low pressures, the quenching effect is often difficult to obtain with small electrodes; several tubes with very small electrodes have, however, worked perfectly and regularly even when a 16 times greater capacity ($13·7 \times 10^{-3}$ mfd.) was employed.

Influence of the Sparking Potential and the Capacity.—On increasing the sparking potential the quenching effect is diminished; the coupling has to be made weaker for the same gas pressure. The limit appears to be the potential corresponding to a spark length of 2 cm.

The influence of capacity is very small; with the same tube good results were obtained with capacities as widely divergent as 10^{-4} and $24 \cdot 10^{-3}$ mfd.

Use of Two Quenching Tubes in Series.—The quenching effect is improved by using two tubes placed in series, and with this arrangement a tighter coupling can be reached if required. Both tubes must naturally have about the same quenching effect, as otherwise the addition of a badly quenching tube would have no effect. The following figures show the advantage obtained by the use of two tubes:—

	Maximum coupling		Current.
Aluminium tube I.	5 per cent.		2·9 amperes.
Aluminium tube II.	6 „		2·95 „
Aluminium tubes I. and II.	10 „		3·25 „

It does not follow that the efficiency is increased, since with the two tubes the resistance is greater than with a single tube; but by the use of two tubes in series a good quenching effect could be obtained at the higher potentials, regular quenching being obtained with a spark length of 3 cm., and even with 4 cm. a considerable improvement was observed, as well as an increase in the current.

The Efficiency with Shock Excitation.—The efficiency with the shock method of excitation is the greater the less energy is used up in the exciting circuit till extinction takes place. The total output is determined from the relation $A_1 = \frac{1}{2} N C_1 V_1^2$, where N_1 is the number of sparks per second, C is the capacity and V the sparking potential. The output A_2 of the oscillating circuit can be obtained in the case of shock excitation, simply from the ammeter reading and the resistance, which latter can be either calculated from the resonance current, or else measured by insertion of an additional resistance in the circuit. The efficiency is then given by the ratio A_2/A_1. Efficiency measurements, with shock excitation, but without quenching tubes, and for longer spark lengths, were carried out, using silver and also magnesium electrodes. The following results were obtained with silver electrodes 5 cm. in diameter; the potential was obtained from Müller's results:—

Spark length.	Kilovolts.	A_1	A_2	Efficiency.
0·5 cm.	17·6	0·83	0·52	52 per cent.
1·0 „	31·4	1·42	1·51	47·5 „
1·5 „	44·3	1·75	2·30	36·3 „
2·0 „	56·0	2·05	3·15	31·2 „

In the case of magnesium the efficiency at all spark lengths is never greater than 22·7 per cent.; with silver, as can be seen, the efficiency increases rapidly at the longer spark lengths.

Efficiency with Quenching Tubes.—The following results were obtained with the same arrangement as above but with quenching tube in circuit. Magnesium electrodes were used.

	Spark length, in cm.	Kv.	A_1.	Amps.	A_2.	Efficiency p.c.
Aluminium tube.	0·5	17·6	1·0	0·92	6·34	63·4
	1·05	33·0	3·51	1·80	2·43	69·2
Silver tube.....	1·83	52·4	8·86	3·45	6·90	78·0
	2·45	64·5	13·4	4·40	11·3	83·7
One copper tube	1·0	31·4	3·0	1·95	2·2	73·2
	2·0	56·5	9·75	3·80	8·37	86·0
Two copper tubes	3·0	80·4	19·7	5·25	16·0	81·0
	4·0	102·0	31·6	6·6*	25·3	80·0

The determination of the efficiency is naturally attended by an uncertainty of some few per cent.; the efficiency is, however, certainly higher with copper and silver tubes than with magnesium and aluminium tubes, and is also higher with small electrodes than with large; it also increases with the sparking potential up to a maximum at 2 or 2·5 cm., actually reaching 86 per cent. with potentials of 30,000 volts and over. The efficiency is not noticeably dependent upon the resistance in the oscillatory circuit. Its high value as obtained in these experiments is attributable to the small losses in the exciting circuit (owing to the compressed gas condensers, heavy connecting leads, &c.) The losses in the condensers with shock excitation are not so important as in the case of ordinary excitation; but still, on substituting Moscicki condensers for the compressed gas condensers, the ammeter reading was reduced by 16 per cent., and the efficiency sank from 80 to 69 per cent.

Experiments with Higher Powers.—To arrive at larger outputs there are three means available: Increase of voltage, increase of capacity or increase of rate of sparking. The best voltage as regards efficiency, as has been seen, lies between 30,000 and 60,000 volts, while to arrive at large capacities the gas condensers available were insufficient. Moscicki condensers were, therefore, used. The spark rate was increased by using a Boas resonance transformer, with which considerably greater powers were obtained up to 1 kw. The transformer was supplied with alternating current at 50 cycles per second, and gave, according to the sparking potential, 100, 50, 33, &c., sparks per second. The quenching effect was secured by the employment of the same quenching tubes as were used before, the heating, even with ½ kw. passing for a whole hour, being quite small, only warming up the oil bath (of 2 litres' capacity) about 12° C.

With a low spark frequency the results were practically the same as previously; with higher spark rates, 33 or 50 per second, the sparks became irregular and the efficiency somewhat low, in no case rising above 47·2 per cent. Rotation of the electrodes showed no improvement, but an air blast directed on to the gap served to make the quenching effect and also the ammeter reading very regular for a considerable period, the sound of the spark assuming a quite musical tone. The efficiency is also improved, as will be seen from the following table, which gives results obtained with a tube having copper electrodes

	Spark length.	No. of sparks per sec.	A_1'	Amps.	A_2	Efficiency p.c.
Mg spark gap	0·5	100	52	1·9	26·4	50·7
	0·75	50	140	3·0	65·7	46·9
	0·75	100	200	3·6	94·6	47·3
	1·0	100	400	5·5	221·0	55·2
	1·5	100	820	7·2	379·0	46·2
Ag spark-gap	1·0	50	232	4·0	—	50·4
	1·0	100	420	5·7	—	50·5

In some other experiments with two aluminium tubes in series, with $A_1' = 950$ watts and $A_2 = 485$ watts the efficiency was 51 per cent. The value of the efficiency depends upon the right kind of blast being used; but this is a technical matter which can be considered as solved by the air-blast arrangement of the Badische Anilin-und Sodafabrik. The efficiency of 55 per cent., it should be borne in mind, includes the loss in the resonance transformer, the charging loss at low frequency and the discharging loss at high frequency in the Moscicki condensers. Allowing for these, the efficiency of the shock excitation alone reaches here also the high value of 70 to 80 per cent., as previously found.

The possibility of utilising quenching tubes for the purpose of shock excitation, with small and medium powers, and hence for laboratory purposes, has thus been demonstrated. Whether they are suitable for large powers such as are used in practical radio-telegraphy depends chiefly upon whether it will be possible to make tubes which can support continued heavy loads. The previously described forms of tube easily become spoilt when subjected to long-continued discharges from the resonant transformer; firstly, because of the electrodes becoming heated, and then owing to the glass cracking at the leading in point of the platinum wires; but, above all, a gradual change of the electrode surface sets in, which shows itself in the fact that the points of light which accompany the strong discharges gradually disappear from the surface of the electrodes, and show themselves more around the leading-in wires, where they form a bright bundle of rays. In this manner the glass at these points gets eaten away, and the tube destroyed.

New volumes of "THE ELECTRICIAN" *commence in April and October.*

(This charge includes all Supplements.)

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the 1911 Edition sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription, 5s., post free.

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Now Ready.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d. *Now Ready.*

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms only, bound strong cloth. Price 5s. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY. AN ELEMENTARY TREATISE FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gelpel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By C. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. [Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton. M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated. Prize 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free. [Price 3s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. A COMPLETE TREATISE. *Ready shortly.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Hönner, by Justus Eck. *In Preparation.*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1878).

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON

(ONLY ADDRESS.)

Tel.: Holborn **6363** (Two Lines). *Tels.:* ELECTRICIAN NEWSPAPER LONDON.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

SPECIAL NOTICE.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

THE REVIVAL OF THE PRIMARY BATTERY.

Some 20 years ago there was no more popular subject than the primary battery and its possibilities in regard to the supply of energy for lighting. In the minds of the general public there was always a good chance of the battery competing against a public supply, and arguments to the contrary were generally of little avail. Even when it was realised that zinc was an expensive metal for the purpose of generating electrical energy in competition with coal, the possibility of using bye-products was brought forward as a further argument in favour of the primary battery. This idea was carried so far that the chemica products were apt to be looked upon as the main part of the business, and the supply of electrical energy as the bye product. There was always wanting, however, a sense o proportion in the minds of the promoters of such schemes and failure was the natural result.

In later years the zinc battery was dropped for thi purpose in favour of the carbon-consuming cell. The ide of obtaining electrical energy direct from carbon instead o using a roundabout method of combustion coupled witl thermal and mechanical transformation has always bee fascinating, and many people have worked at the idea; but

Digitized by Google

unfortunately, carbon as an element is particularly ill-qualified by Nature for the production of electrical energy voltaically. Whether some other method of using carbon for this desirable end will be evolved, time will show; certainly at present there does not seem much prospect of producing a carbon-consuming cell pure and simple. In some cells, such as that of BORCHERS, it has been assumed, without any good evidence, that the carbon is oxidised voltaically; and in others, such as that of JACQUES, that voltaic action was the source of E.M.F., whereas a thermo-electric origin is much more probable.

We need scarcely remark that the day has long since passed when zinc was regarded as a possible competitor of coal. This, however, does not mean that a good primary battery would not be an extremely useful piece of apparatus. The defects of the usual primary cell are want of convenience, want of cleanliness, and the fact that the current falls off, due to polarisation, after a comparatively short time. When once the current has begun to fall seriously then there is nothing to be done but to re-charge the battery, and this is generally an operation that is by no means convenient.

Elsewhere our readers will find an account of the Benkö primary battery, as described by Mr. W. R. COOPER in a Paper accepted by the Institution of Electrical Engineers. This battery is of considerable interest, as it appears to utilise a new principle of overcoming polarisation. To this end the electrolyte is allowed to flow through the carbon plate continuously, so that the reduced products caused by polarisation are removed as rapidly as they are formed, and therefore the current can be maintained at its proper value up to a certain limit so long as this flow of electrolyte continues. Owing to the special construction adopted, the output obtained is very high, the resistance being particularly low. Since the battery uses zinc and a bichromate solution, it need scarcely be said that the cost per kilowatt-hour is necessarily high compared with the cost of energy obtained from public mains. Further, the cost of energy will depend upon the way in which the battery is used—that is, whether it is so used that the electrolyte is fairly exhausted or so that a good deal of waste takes place. On the other hand, the first cost of a battery of this kind is quite low compared with the cost of the usual generating plant consisting of an oil engine set, and but little space is required. It must be remembered that the use of metal filament lamps on 25-volt circuits has very materially altered the situation, and has rendered very much easier the equipment of quite small installations than was the case a few years ago. Whereas the handling of a battery giving 100 volts might be troublesome, the maintenance of a battery giving 25 volts would be a small matter in comparison. There are many small country houses where electric light would be much appreciated, but whose owners are unwilling to spend money on oil engines and plant of the kind requiring rather special working; yet such people would frequently not object to paying a somewhat high price per unit if the energy could be obtained conveniently. It seems not unlikely that the Benkö primary battery, if properly developed, will meet cases of this kind and will cause an extension of electric lighting in directions where it is not at present available.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Notes on Applied Mechanics. By R. H. WHAPHAM, M.A., B.Sc. and G. PRECE. (London: E. Arnold.) Pp. 206. 4s. 6d. net.

It is pointed out by the authors that this work is primarily intended for the use of Naval Cadets who are being trained under the New Scheme, after they leave Dartmouth, for their six months' work in the two training cruisers. It is the outcome of experience which has been gained in teaching on board those ships, and deals with as much of the subject as can be covered during that period without running the risk of substituting mere cramming for careful and systematic teaching. From this it will be seen that the work is by no means elementary in character; indeed it is only suitable for those who have already received a fairly good grounding in mechanics. As is only to be expected, the subjects dealt with are treated principally from a naval point of view, and the majority of examples given, which are all carefully and accurately worked out, are such as would not only be of interest to a naval student, but such as might, and, indeed, frequently would, arise during the course of his work. It is not to be supposed from this that the text-book is only suitable for Naval Cadets; on the contrary, it is a valuable treatise on the subject of applied mechanics, and should be of use and assistance to all students desirous of completing their knowledge.

The opening chapters deal with the fundamental and derived units, instantaneous centres, machines (considerable attention being given to pulleys), and friction and power measuring devices. Perhaps one of the best chapters, although it is difficult to discriminate amongst so many of almost uniform excellence, is that which deals with relative velocities and problems thereon. The explanations are given simply and distinctly; every point that might present difficulty is made clear, and the examples chosen are such as are of special interest to all whose work is or will be in connection with machinery. Other chapters deal with kinetic energy and momentum; flywheels; simple harmonic motion; engine problems, including curves of effective steam pressures, and crank efforts; stress and strain; bending moment and shearing force; beams and struts; torsion; frameworks, &c., and projectiles. The range of the book is, as will be seen, wide, and it is difficult to mention any portion of the subject that has not received adequate treatment. The authors are to be congratulated on the able manner in which they deal with the various points, and the work is one which can be recommended to all who wish to improve their knowledge of applied mechanics. G. B. B.

Physics. By C. R. MANN and G. R. TWISS. (Chicago & New York: Scott, Foresman & Co.) Pp. 424.

This work, which is intended for beginners in the subject, is divided into two parts. Part I. consists of 15 chapters, pp. 17–299, dealing with Mechanics, Heat, Electricity and Magnetism, Sound and Light; and Part II. contains an additional six chapters, pp. 303–417, treating of the more difficult points encountered.

The book aims at removing what the authors claim to be a common failing in the elementary teaching of physics—viz., that "Definitions, laws and principles are simply stated, memorised by the pupils and justified afterwards, if at all, by illustrations in the way of experiments and practical applications." They claim that a method of treatment that develops the subject from the concrete experiences of the learner is the only method that gives mastery of the subject-matter, and provides the pupil with real training in scientific thinking. Probably it is safe to say that the majority of teachers would support this view.

The authors, in accordance with these ideas, consider it necessary to postpone the subjects of velocity and acceleration, absolute units of force and energy, coefficients of expansion, &c., to the second part, and omit altogether such matters as magnetic moments, the tangent galvanometer and terrestrial

Digitized by Google

magnetism. Moreover, they discuss lenses before mirrors, and colour is studied before refraction. But, on the other hand, we find included many points not often mentioned in elementary text books—*e.g.*, the D'Arsonval galvanometer, electric motor, dynamo, telephone, telegraph, three-colour work, aeroplane, steam turbine, wireless telegraphy, electron theory, radium, &c. The result is a most "readable" book, perhaps one of the most interesting works on elementary physics that could be found.

There are 220 illustrations and three plates, and a good summary, and a set of really excellent questions is provided at the end of each chapter. B.W.C.

The Standard Handbook for Electrical Engineers. Third Edition. (New York: McGraw-Hill Book Co.) Pp. xii. + 1497.

It is less than two years since we received the first edition of this Handbook; but already a third edition has made its appearance. In view of the fact that the number of pages has been increased by about 270, it is evident that considerable alterations have been made in the text. In this connection the publishers believe the present edition to be a triumph for the "unit" system on which the book was compiled, and which permits thorough revision of any part of the work. The need for such a thorough revision as is mentioned in the preface certainly somewhat reduces the value of previous issues.

The Handbook still comprises 20 sections; seven of these are contributed by Mr. O. A. Kenyon, who is also joint author of three other sections. Section I., dealing with units, has received little alteration. Section II., however, has been considerably enlarged, the general theory of electric and magnetic circuits having been entirely rewritten, and the calculation of inductance and capacity being given in greater detail. Descriptions of several new instruments have been included in Section III. on "Measurements and Measuring Apparatus."

The greatest addition, however, has been made to Section IV., relating to the "Properties of Materials," which has been nearly doubled in length. We notice that the term "aluminium" now replaces the Americanism "aluminum" in the Tables. The article on the magnetic testing of iron has been entirely rewritten, and now deals very fully with this subject. A valuable addition is also the sub-section giving data of a large number of resistance alloys.

As it is impossible to refer to all sections in detail it must suffice to say that the chief alterations and additions have been made to those parts of the book which treat of transformers, motors, central stations, transmission and distribution, electric locomotives, telephony and standards.

An improvement that will be appreciated by the busy engineer is the thumb index to the various sections.

HIGHER TECHNICAL INSTRUCTION.*

BY J. H. REYNOLDS, M.SC.

Summary—The author discusses the reasons why this country is behind other countries in regard to education. In spite of the fact that the facilities for higher technical instruction have been considerably increased, the number of students studying science as applied to manufacturing industry is small. The author especially pleads for a keener appreciation of the value of knowledge and the subordination of the passion for games.

Owing to the absence of any returns which give, with even an approach to accuracy, any information as to the number and quality of the students engaged in higher technical instruction, it is extremely difficult to make fruitful comparison between the facilities offered in the United Kingdom and those available abroad, especially in Germany. Whilst we have the present confusion in our statistics, we can never hope adequately to realise our true position in relation to foreign nations, especially to those who are our commercial and industrial competitors. It is not, however, by a mere comparison of technical institutions or of students enrolled in them that we can arrive at a true estimate of the relative position of, say, Germany and the United Kingdom. We must know something of the range of studies, of the length of school life, of the methods of instruction, and of the attainments reached by the pupils of the secondary schools, since it is to them that the universities and the technical high schools of the nation must look for students. It is high time that the secondary schools—or such of them as can present satisfactory credentials—should receive State recognition, and be relieved from all external examinations, and their leaving certificates (duly safeguarded as to subjects and length of course) be accepted by higher institutions of learning throughout the Kingdom as giving complete and satisfactory evidence of fitness to enter upon a further stage of advanced study. In my opinion no reform is more urgent than this.

Forty-two years ago there was published in this country a book than which there has been nothing either said or written which more plainly puts before the nation its educational needs and the right measures to supply them. I have in mind J. Scott Russell's epoch-making book "Systematic Technical Education for the English People." The author came to the conclusion that the English nation was nearly the worst educated of the peoples of modern Europe, but that no people would be more responsive to the pains and care of the statesman who should undertake measures for their general, scientific, and technical education. And now, in 1911, the pleas and remedies put forth in Scott Russell's book of 1869 remain as cogent and as greatly in need of enforcement as on the day they were written, and as directly applicable to the present conditions of industry. We were a generation behind the German nation in 1869, and we are hardly less so to-day.

The reasons are not far to seek. For the first three-quarters of the 19th century our people were neglected by their leaders. Neither elementary, nor secondary, nor university education received attention. Not so with Germany. The progress of scientific discovery found Germany ready. In her numerous universities and technical high schools there were men in large numbers who, by reason of their scientific training, were prepared to take advantage of possible scientific industrial developments. In no other way can the phenomenal advance of the German nation be explained, and the evidence of this advance is seen in her enormous output of fine chemicals—which has enabled her to put the whole world under toll—in her great mechanical and electrical engineering developments, and in her mercantile marine. She has created, as Bismarck described it with a certain cynicism, an educational proletariat; but this only meant that she had at command a vast supply of educated labour, the very instrument needed to turn scientific discovery to practical account.

It is perfectly true that we, too, have made great advances in all departments of education in the 40 years under review, but we cannot leave out of consideration the fact that Germany was in a position which enabled her at the very beginning to seize the opportunities offered. Thus, whatever be the progress we have made, the advance of Germany has been maintained, and in some departments of industry her position is now apparently beyond serious challenge.

How then do we stand from the point of view of our educational means and resources? We are only just beginning to make really effective our facilities for secondary education. The average school life of the pupils in our secondary schools is, however, hardly more than three and a half years, possibly less. So long as this prevails there cannot possibly be any satisfactory supply of students to the universities or to technical schools of high grade, nor can the teaching in these institutions be of a satisfactory standard.

We have largely increased our facilities for scientific education. The United Kingdom now boasts 18 teaching universities as compared with half that number 60 years ago, and the enrolments, including the students in university colleges, possibly reach 40,000. In the 22 universities in the German Empire, the enrolments are nearly 58,000, but to these must be added the students enrolled in the 10 technical high schools, namely, 15,885, making the total enrolments nearly 74,000, whilst the age of entrance and the state of preparation required is admittedly much beyond that prevailing in this country. By the recent regulations entrance to the technical high schools requires not only the certificate of complete attendance at a Gymnasium or Real Gymnasium or an Ober-Realschule, but a year's preliminary experience in a works as well. This all helps to establish a position of intellectual strength which goes far to explain the industrial and commercial position of Germany to-day.

It is extremely important to remember the extent to which this country is dependent upon foreign sources for the supply of raw materials for conversion into articles of use, and that in this regard it enjoys no advantages, as it did formerly, over such nations as Germany or the United States. Even the advantage which we enjoy in the supply of fuel ready to hand as a source of cheap power is no longer largely neutralised by the advent of electricity. And because of the very prodigality of our resources in coal, we have neglected in large measure to study the best methods of its conversion into power. Witness for example the production of coke used for metallurgical purposes. Our method of production by means of wasteful over

* Abstract of a Paper read at the Imperial Education Conference.

Digitized by Google

of the beehive type has been entirely superseded by those devised in Germany, and firms in this country building coke ovens accept designs of German or continental origin. The truth is, we have got to realise the hard fact that material conditions are tending towards equilibrium, and that superiority can only be maintained by a sedulous cultivation of brain power and a firm discipline.

The facilities for higher technical instruction in the United Kingdom it must be admitted have been largely increased, in considerable measure as the result of the Technical Instruction Act of 1889 and the Customs and Excise Act of 1890, yet it is certain that the number of students in our universities who are studying science with a view to its industrial applications is small by comparison with those so engaged in universities and technical high schools abroad; and still more unsatisfactory is the small number, having regard to the enormous industrial enterprises in which the nation is engaged, and which gave it at the present time the first place in the whole world.

Of the 74 technical institutions which comprise the Association of Technical Institutions, only 27 have any day-students over 16 years of age taking 20 hours per week in science as applied to manufacturing industry, and the total number so engaged is only 1,842, or less than half the number to be found in the Technical High School of Charlottenburg, or of Munich, or of the Institute of Technology at Boston. Moreover, the students of the former are enumerated as from 16 years of age in place of 18, and are in most cases admitted on a not very satisfactory standard of examination, and further include subjects in their course to be found abroad only in Gewerbe or special schools. The Board of Education in its report for the year 1909–10, issued only a few days ago, states that—"The total amount of advanced instruction of the kind provided in technical institutions is still disappointingly small. In some of the more important industries as, for example, engineering, the instruction is largely utilised by students; but in a great many others the supply of students is very small. It is to be deplored that there are several schools in which the well-equipped staffs and the excellent equipment practically stand idle in the day-time through lack of students."

Out of 3,400 day students enrolled in recognised technical institutions in 1908–9, there were 211 students under 16, and only 1,990 took full courses of instruction. Of these, 406 were engaged in work of the third year, and 125 in still more advanced work.

As an illustration of the *different* attitude towards technical training of an advanced character mainly devised for men intended for responsible positions, the present author submits a statement respecting the textile schools in this country and in Germany.

To those desirous of pursuing the subject of technical training, I can commend nothing better or more stimulating than a careful perusal of the Diplomatic and Consular Reports on Scientific and Technical Education in the German Empire, prepared by Dr. Rose, and issued by the Foreign Office. They are a mine of information, and show with striking clearness the wealth of provision made to supply efficient training in every industry of importance, and for all grades of their service. We suffer in this country from a want of appreciation of the value of scientific knowledge and investigation and its application to manufacturing industry—first by the employers and directors of industry, and second, by the immediate managers, whose indifference often amounts to serious hostility. Not until our great industrial concerns are recruited more largely than is now the case from the product of the schools will there be any serious change in this regard.

There is not only the indifference of employers and mangers to contend with, but the short-sighted policy of parents and students, who take the most empirical views of the training upon which they either desire to enter. It is imagined that technical training is a mere matter of manipulation, of dyeing without a knowledge of chemistry, of engineering without an efficient training in mathematics, mechanics, and physics. It is not sufficiently realised that the training given should put the student in the position, not only of clearly understanding the *raison d'être* of the processes in which he will be engaged, but of being able to appreciate the value of problems as they arise, and to enter intelligently into their careful investigation.

No one doubts the Englishman's capacity—there is striking evidence of it, both at home and abroad; it is his salvation, but as a friend of a large American engineering firm in this country, himself a technical high school graduate, once said to me, "I am astonished at the capacity of the Englishman, but why does he not add knowledge to it?"

I would not have it understood that there has not been in the last few years a very considerable change for the better in the attitude and sympathy of employers in their appreciation of scientific and technical training. Many large firms and some public companies have well-known schemes and conditions of admission to their service requiring, according to the position sought, certain definite attainments. It would be of great public advantage if there were published a list of firms and of public departments who have definitely laid down schemes of admission to their service based upon educational requirements, and such firms will gain enormously by their enlightened policy. Moreover, there would further be a great advantage if in Government and municipal undertakings there were offered definite opportunity of practical experience, if only for a limited time, to duly accredited students.

As a nation, we show ourselves impatient of theory, and place our faith in the practical man. We have had, perhaps, some justification for this in the past conditions of industry, but the progress of science has made the theorist indispensable. It can be shown conclusively how completely modern industrial developments find their beginnings in the long-continued, patient investigations of the scientific man in the laboratory, equipped with implements of precision, and conditions indispensable to exact and fruitful research. We cannot afford that all this work, depending upon high scientific training and upon the application of the finest scholarship, should be done mainly abroad.

The provision for higher scientific and technical instruction in evening schools since the Technical Instruction Act of 1889 has much increased in volume and in quality, and in late years especially in efficiency of organisation, but from the very nature of the conditions it is not possible to give, except to a limited extent, really advanced teaching in science or technology to evening students. Indeed it is only possible to arrange it in localities exceptionally situated, where the population is large, and where the industrial conditions are such as to attract a high type of workers. It is in the North especially where these conditions prevail. And as to higher technical instruction, so important to those engaged in industry, the records of the Board of Education and of the City and Guilds of London Institute show only a very small proportion of successes in the honours stages of the various science and technical subjects.

My words are a plea for a keener appreciation of the economical position, of the value of knowledge, of the need of sound theory, of the necessity for a more determined sacrifice of time and money, and especially are they a plea that our young men should subordinate the passion for games, which seems on the increase with all classes, to a keener intellectual zest. How few of our college students in the precious closing years of their student life are content to shorten a summer vacation that they may take advantage of practical experience in the factory, or mine, or workshop? Yet this, as I well know, is a commonplace with a foreign student.

I am keenly sensible of the struggle into which we have entered with the best-equipped nation in the world so far as education is concerned, and I do not wish to see my countrymen fall behind in the race because of lack of enterprise or of shortcomings in education, and I am sure I speak the mind of the best men of our nation, who, in no alarmist spirit, but in cool, calm judgment, declare that her doom is surely set, unless, with the courage that has hitherto never failed us, we rise up and provide for our people the means of the highest education, alike in their best interests as human beings and as needful for the maintenance and development of her trade and industry.

CORRESPONDENCE.

THE ORIGIN OF "ATMOSPHERICS" IN WIRELESS TELEGRAPHY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The thundery weather of the past few days has given me an opportunity of proving, beyond a doubt, the cause of at least the far larger proportion of the atmospherics, or Xs, so troublesome in wireless telegraphy. The observations were made at a small station at Bushey, which I have recently put up for the purpose of studying these phenomena.

The enormous increase in the number of Xs observed at the station on Wednesday evening, when severe thunderstorms were taking place in Devonshire, is merely a confirmation of my previous observations. The actual proof of the origin of Xs was not made until Saturday night.

At about 8 p.m. on Saturday evening a sharp thunderstorm passed over the station and travelled off in a north-easterly direction, leaving the sky clear overhead. The thunder soon became inaudible, showing that the storm was at least 15 to 20 miles off, although flashes occurred very frequently in the bank of clouds on the horizon. At 8:45 p.m. I commenced to observe these flashes, at the same time listening in my wireless

Digitized by Google

receiver. *At every flash, and absolutely simultaneously with it, an ordinary X was audible.* At about 9:24 p.m. two flashes occurred in quick succession in the same locality—a phenomenon I have frequently noticed in thunderstorms—in the telephone of the wireless receiver there was simultaneously audible the double knock so characteristic of many Xs. Later on a flash produced a sharp hissing X, lasting an appreciable fraction of a second. This flash was no doubt a quick succession of partial discharges, though these followed so rapidly as to be indistinguishable to the eye as separate flashes. Visual sensations being semi-permanent, it is, of course, difficult to distinguish successive flashes from one another unless they are separated by quite a large fraction of a second.

In all I observed from 40 to 50 flashes during the evening.

My conclusion is that every visible flash without exception gave rise to an X, also that the single knock, double knock and the short hiss or rattle are produced by discharges apparently common in any ordinary thunderstorm.

Having thus established that every distant flash is the cause of an X, it is of interest to estimate roughly the number and distribution of thunderstorms requisite to provide the Xs actually observed in wireless stations. On Saturday, the storm being a comparatively small one, flashes occurred at intervals of from one to two minutes. Very much greater spark rates are often observed. From my own experience I may mention three cases. The first was at Rouen, in the valley of the Seine. The thunder rolled absolutely continuously for 43 minutes. There was no rain, and during the whole time the sky overhead was lit up with a succession of flashes so rapid as to produce an apparently continuous shimmering light on the houses opposite my window. The second was on the Firth of Clyde, when over 900 flashes were counted in three hours, giving an average of over five flashes per minute. The third was in the Highlands of Perthshire. Here the thunder rolled practically without cessation for two hours and a quarter, flashes being almost as continuous as in the storm observed at Rouen. One such thunderstorm, taking place anywhere within one or two thousand miles, is therefore alone sufficient to account for all the Xs observed at a station during any bad period of several hours, for I have just shown that every flash produces an X.

It is well known to meteorologists that in certain districts, such as Western Tropical Africa, there are, on the average, many thunderstorms every day. From this district therefore must come an almost constant stream of Xs. Their number will, of course, vary with the seasonal and daily variations of thunderstorm frequency already known to meteorologists, and their effect on distant stations will, in addition, vary with the variations of transmissibility of electric waves known to wireless operators.

It is probable that the hissing atmospherics of long duration occasionally observed may be due to brush discharges from the aerial itself. I have not as yet noticed any of these at my Bushey station, but this may be due to the fact that my aerial is a very low one.

It is clear from my observations, however, that ordinary Xs are due to electric waves radiated from thunderstorms, since the simultaneity of lightning flash and X has been proved directly with great accuracy by the coincident perception of the light waves and electric disturbance by the eye and ear of the same observer.

In the near future I intend to erect a directive system of aerials, and thus determine the directions of the thunderstorms responsible for the Xs observed at the station. The results to be obtained should be valuable not only in wireless telegraphy but also in meteorology.—I am, &c.,

London, May 15. J. ERSKINE-MURRAY.

VACUUM METHOD OF FILLING CABLE JOINTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In THE ELECTRICIAN for March 24th, 1911, I find a description of the vacuum method brought out by the Allgemeine Elektrizitäts Gesellschaft for driving off moisture from the joints in filling up high-tension cable boxes.

It is interesting to note that a method practically the same as this has been in use, at the suggestion of Messrs. Pirelli & Co., cable makers in Milan, by the Edison Co., in Milan, since 1896, when laying certain 3,600-volt three-phase cables. I may say that the system then employed was, perhaps, simpler, as it required only one opening in the box. There was a vacuum pump, hand driven, a funnel of the same shape as that described by you with valves, gauge and all the rest.

The system proved very satisfactory and was used extensively for many years; but later experience taught us that by using good quality compound and taking special care, such as heating the box well before the operation, the ordinary way of filling was quite safe even for extra high tension; so that the method was considered as an exaggerated precaution, and was abandoned.—I am, &c.,

Società Generale Italiana Edison di Elettricità,
ING. T. A. BERTINI,
Milan, April 28. Il Direttore Generale.

IMPERIAL TELEGRAPHS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should like to make a few observations in reply to Mr. Neilson's remarks (as reported in your issue of the 28th ult.) regarding the Paper I recently read to the Royal Colonial Institute.

Possibly because, in common with everybody else, Mr. Neilson had not the Paper to study in advance, he made certain criticisms which he would not, I think, have made had it been otherwise. For instance, he says: "If traffics were greatly increased by reduced rates the number of cables would have to be increased." The last 13 lines of page 3 of my Paper (enclosed herewith) clearly state this. Again, where Mr. Neilson criticises my proposal of an all round Imperial rate he appears to forget my pooling suggestion.

Mr. Neilson said that "he thought the idea that wireless was on the eve of taking the place of cables was a little previous." Can Mr. Neilson—or can you, Sir—show me any passage in this Paper where I make such a suggestion as this? On the contrary, have I not clearly indicated that I regard the wireless telegraphy of to-day more as an adjunct to cables than as a substitute for them?

Mr. Neilson says "the greatest desire of the Government was for the security of communication. That took first place, and was far beyond cheapness." Exactly; and I have not said anything to the contrary in my Paper—though I consider there is also a need for more favourable tariffs. On the other hand, I clearly stated that, in my view, to better secure this much desired "security," certain additional lines should be laid on routes widely different to any existing route. Notwithstanding his remarks about "security," Mr. Neilson appears to consider we are just right in this regard at the moment; for he says: "At all events, the cables provided so many alternatives that it would be hardly worth the while of foreign Governments to cut some of them." My view is that the more cables we have on entirely different routes the greater our degree of safety, and at present this degree is not of a very high order. The position was, however, immensely improved by the All-British Pacific Cable, previous to which our communication with Australia depended upon the eastern route through the foreign regions of the Mediterranean Sea.

It is, I suppose, but natural that outside suggestions of new lines should be opposed by existing cable systems. At one time Sir James Anderson (late managing director of the Eastern Associated Companies) spoke warmly against a cable "all the way from Australia to Mauritius, across the route of the trade winds, to the Cape," whilst adding, "there is not even a sand bank on which to catch fish; there is not a port to which a cruiser or a cable ship can replenish their supply of coal, which they are certain to require to do. There are no ships going there; there is no trade and nobody wants to go there."* The Admiralty, however, thought differently; and contemporaneously with the "All British Pacific Cable"

*"Proc," Roy. Col. Inst., Vol. XIX., p. 213.

Digitized by Google

this line was undertaken, under subsidies, as an "Eastern" enterprise, some four years after Sir James Anderson's remarks thereon. It is now, I suppose, recognised as serving an eminently useful purpose, though as warmly criticised beforehand as the All British Pacific Cable still continues to be by those interested in a rival system. The Pacific Cable was additionally said to be impracticable as an engineering work, yet it was laid without a hitch and has never given a moment's anxiety.

Mr. Neilson says: "I do not think Mr. Bright has allowed sufficiently for the danger of ice." On pages 13 and 14 (where indicated) you will observe that I distinctly referred to this objection to all extreme northern routes; and with regard to the rest of his remarks—putting aside the question as to whether he is a better authority than myself as to what "a responsible engineer" would do—I will remind Mr. Neilson that in the year 1906 the Telegraph Construction & Maintenance Co. landed a cable (of a special type) on the coast of Iceland and that this has never given any trouble since.

In closing his remarks at the meeting, Mr. Neilson criticised my views as "large." The Cable Companies came into existence and retained their high estate solely due to the "large views" and enterprise of men like the late Sir John Pender. I might add that it would be strange if only the lines undertaken from time to time by a certain group were good for the nation and Empire.—I am, &c.,

Westminster, May 9. CHARLES BRIGHT.

We have submitted Mr. Bright's letter to Mr. Neilson from whom we have received the following reply:—

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—With reference to Mr. Bright's letter I would first point out that he has already had his proper opportunity—and rightly availed himself of it—of replying to the other speakers and myself at the Royal Colonial Institute.

Curiously, he forgets that other views besides his own were expressed on that occasion, to which I naturally referred when speaking, clearly indicating, however, at the time to which speaker I was replying. This simple fact deprives Mr. Bright's letter of much of its point. As there was nothing in his Paper "on this or that subject," then clearly on such matters I was not criticising his views, but those of some other speaker.

Sir James Anderson's opinions as quoted appear to refer to cables laid on their commercial merits. Given sufficient receipts, for instance, his remarks, I take it, no longer apply. Moreover there is much of Mr. Bright's letter with which one does not disagree.

I would only add that to call a suggested cable a "strategic" line, as some do, does not make it so, but only invites the attention of an enemy to it in the event of hostilities.

Thanking you for the opportunity of replying to Mr. Bright's letter, I am, &c.,

City, May 16. GEO. R. NEILSON.

BATTERY ECONOMICS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—While the matter is still fresh in the minds of your readers may I trespass a little further on your valuable space. I will endeavour to be very brief.

I believe the difference of opinion which exists about the relative values of boosters and regulating cells is largely due to personal impressions.

The Britisher comes to the question with the sizes of boosters and cells determined for discharge rigidly fixed in his mind. He compares this with the regulating switches he sees on the Continent, and at once comes to the conclusion that they are too complicated, especially when considering the frightful efficiency of the ordinary type of booster when charging the battery.

But he overlooks the fact that, in following Continental practice, he *must add 20 per cent. additional cells to his battery*, and will now require a booster, *for charging purposes alone*, which is big enough (if made triple-parallel) to deal with his discharge.

What, then, is the objection to using this booster for the discharge? It cannot be on the score of cheapness, for the cost with the booster alone is less than one-third of that with the combined arrangement.

The objections alleged are two:—

1. That the switchgear is more complicated. This is due merely to insufficient information having been given in the paper; for the use of large "selector" switches has been employed, within my own experience, on some of the heaviest direct-current generator panels in the Kingdom for many years with never the least trouble; and the switches would *not be touched* from the beginning to the end of the discharge.

2. That useful current at times of peak is taken up in driving the booster. This is quite true; but useful current is also locked up in idle cells with the regulator method. A consideration of Fig. 4 of my Paper will show that, out of 303 cells, a discharge is obtained which is only equivalent to that from 290 cells fully worked; representing a 4 per cent. loss of locked-up current. With the booster arrangement, for the same size of battery, 6 per cent. of the battery current would be taken up by the booster motor; but out of this energy some 4 per cent *is returned to the battery circuit*; the actual loss being therefore only 2 per cent. Moreover, since the booster only costs about £0·5 per kw., whereas the battery costs about £6·0 per kw., it is obvious that a lot of capital is locked up needlessly in the regulating cells.

It should be mentioned (several speakers having misunderstood this point) that the regulator cells shown in my Figs. 9, 10 and 11 are not really regulating cells at all, but are merely for "floating" purposes, and carry no heavy currents. They can be done away with, if desired, by employing a small "bucking" booster; but 2 or 3 cells are required to compensate for the non-regulating properties of the static booster, where this is employed.—I am, &c.,

Birmingham, May 6. A. M. TAYLOR.

THE DRIVING OF WINDING ENGINES BY INDUCTION MOTORS.

We give below an account of the discussion at the meeting of the Institution of Electrical Engineers last week on Mr. H. J. S. Heather's Paper on this subject. The author being in South Africa, Mr. W. H. Patchell read the Paper and also showed some lantern slides of winding plant in this country.

Mr. W. C. MOUNTAIN considered the Paper written by Mr. Heather of considerable importance and value to the Institution, because it brought forward the possibility and the desirability under certain conditions of using induction motors instead of the Ilgner system; and if it could be shown that winding gears could be economically operated by means of induction motors direct from the supply, he considered that it would be a step forward and tend very largely to popularise the use of electric winding. In considering a problem of this kind the commercial aspect entered very prominently into the case, and, before adopting winding with induction motors supplied direct, one had to consider very carefully the source from which the electric energy was to be obtained. If the supply could be taken from a large power station, in which the fluctuations of current or demand would not be severely felt, then there was no doubt that the induction motor offered a very simple and effective way of dealing with the problem; but if the supply had to be taken from a supply station where the output was limited, then it might be necessary to introduce the Ilgner system or a balancing system of some kind to avoid the heavy peak loads. As an example, Mr. Mountain instanced a winding gear in the north of England which was operated by means of an induction motor of 700 H.P. supplied at 5,500 volts direct from the mains. This motor at the moment of acceleration called for an output from the generating station of 1,700 H.P., and, although this supply was taken from the Newcastle Electric Supply Co.'s power station, which was equipped with eight 6,000 kw. units, five or six of which were probably in operation, every start of the winding gear could be observed in the power station. To consider properly a problem of this kind it was desirable to base one's observations upon a definite problem. He therefore gave some figures from an actual case, and referred to the diagrams reproduced herewith, which represented the working of a

Digitized by Google

winding gear of moderate capacity, for which there was a very large demand, the duty being as under:—

Depth of shaft	780 ft.
Time of winding	40 seconds
Time of banking	15 ,,
Average rope speed	19·5 ft. per second
Weight of coal per wind	2 tons 4 cwt.
Circumference of rope	4 in.
Nominal horse-power of gear	250 to 500
Balance rope fitted	
Time of acceleration	8·5 seconds
Maximum velocity	27·5 ft. per second
Time of retardation	4 seconds
Acceleration	2·73 ft. per sec. per sec.
Retardation	5·8 ft. per sec. per sec.
Maximum velocity	23·2 ft. per sec.
Power consumption with induction motor	2·3 units per wind
Do., with Ilgner system, assuming an efficiency of 70 per cent.	2·7 ,, ,,

The diagrams showed that the horse-power required to accelerate was about 440 in each case, and of course, taking current from the supply company, it meant that a demand equivalent to 440 H.P. would be

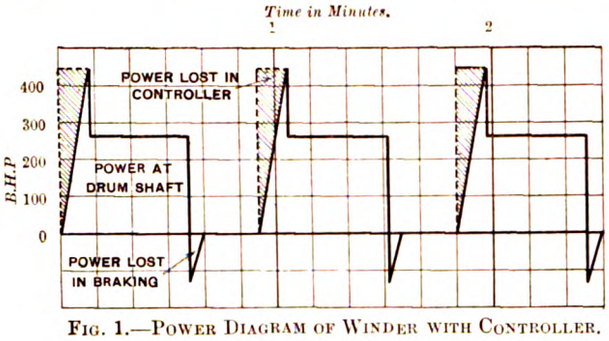

FIG. 1.—POWER DIAGRAM OF WINDER WITH CONTROLLER.

required for each wind; but as the current was switched off the motor before the end of the wind, and no current was consumed between the time of cutting off the supply until the next wind, it would be seen that, although the demand was considerable, the total consumption, allowing for rheostatic losses, was less with the induction motor than with the Ilgner system. They also showed that with the Ilgner system the power supplied to the terminals of the Ilgner set was equivalent to about 215 H.P., or about half the demand of the induction motor set, assuming that the load would be practically constant, although it would not be quite so in practice. The final result, therefore, was that the actual energy consumed with the balancer set slightly exceeded the consumption in the plant fitted with the induction motor. One had also to consider in dealing with any question of winding the desirability of making the winding plant as simple and as efficient as possible, and also capable of ready repair. With the Ilgner type of winding there was a certain

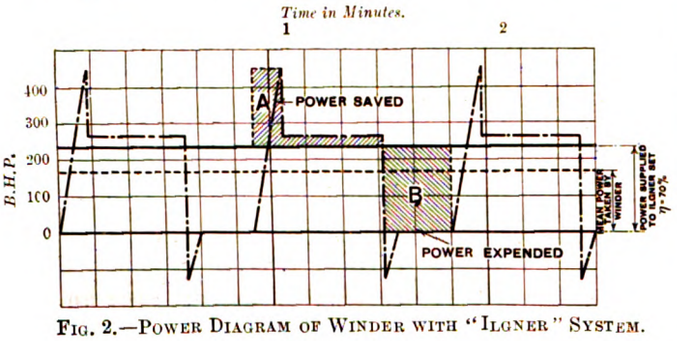

FIG. 2.—POWER DIAGRAM OF WINDER WITH "ILGNER" SYSTEM.

amount of risk due to there being so many links in the chain—*i.e.*, a motor on the balancer, heavy flywheel running in two bearings, a generator, and also the switchgear and the motor on the winding gear—all of which were liable to go wrong; and, as a matter of fact, he knew of one case where the colliery had been laid off for six weeks due to a burn-up of the motor on the balancer set. It would be an advantage if balancing were adopted if the balancing set could be designed so that it would enable the motor in case of emergency to take the supply from the mains direct; but if induction motors were used for this purpose, he considered that, in preference to using a high voltage on the winder motors, it would be desirable so to wind them as regards voltage that the windings could be as simple as possible, preferably plain copper bars in mica tubes with sweated end connections in both stator and rotor. This would render the machine almost perfect as regards simplicity and freedom from breakdown, and he did not consider that with a motor of this type the additional cost of the transformer which would be required would come to very much more than a high-tension motor. There was undoubtedly, not only in this country but abroad, a very big field for electric winding gears, and he had found from experience that for moderate outputs—which would cover a very large field—the geared type of winder with machine-cut helical gearing and moderately low-speed motor, formed a very efficient and satisfactory type of plant, and such an arrangement could be easily fitted with a simple induction motor with rheostatic control, forming, when the conditions of supply admitted, a very economical and satisfactory arrangement.

Mr. G. STJERNBERG could not quite agree with the author as to the efficiency of the induction motor wind. The efficiency with that system depended upon the number of winds. It would be measured not by the average or maximum speed, but by the energy used. The motor losses in both systems were not materially different. In the Ward-Leonard system he put the efficiency at about 0·73 and with the induction motor 0·8. If the ratio of the average speed to total time increased the efficiency decreased. With the Ward-Leonard system it decreased slowly, but with the induction motor quickly. A low limit for efficiency for the Ward-Leonard system would be 0·55, but with induction motors it would be something like 0·35. With the Ward-Leonard system there was no connection with the main circuit; it worked better, and was considered very safe indeed. As to brakes, perfect mechanical brakes were available. The energy stored in the sinking load would be, of course, entirely lost, but there was no limit to the load that could be let down the shaft.

Mr. G. STONEY referred to a 700 H.P. induction motor winder which had a peak load of about 1,700 H.P., and this caused a perceptible fluctuation at the power station, even when the total load was about 30,000 kw. If several winders of this class were connected to a power station it was likely that the fluctuation would be sufficient to be objectionable on lighting circuits. Of course, if a very large number of winders were connected the fluctuations would be much less, as in the case of large tramway stations. One point about the Ilgner system, apart from cost and efficiency, was that the maximum demand was reduced to about one-half. It seemed, therefore, to him that in some cases where there were four cages in the shaft and induction motor winders were used, it might be possible to arrange that one pair of cages were running while the other were standing, and this would bring about much steadier load, as in winders the periods of no-load were approximately equal to those of full-load.

Mr. C. H. GADSBY asked Mr. Patchell, with regard to the winding plant shown in one of the photographs, which plant appeared to have a direct-coupled motor and the winding drum to be some 12 ft. or 14 ft. in diameter. He had been recently engaged on the design of a somewhat similar scheme, and found that, to have anything in the way of a large winding drum gave an enormous rope velocity with any ordinary speed and a direct-coupled induction motor. He would be glad if Mr. Patchell would say what was the rope velocity and the speed of the induction motor in the instance shown.

Mr. B. M. JENKIN, in a written communication, said that it had been pointed out that the maximum demand on the supply when using the Ward-Leonard control system with the Ilgner flywheel was about one-half the demand when using the direct-connected induction motor. From this it was argued that with current from an outside supply the induction motor could be used, as the peak would have to be dealt with by the supply company. The charge for current, however, was often partly based on the maximum demand, so that the owner might wish to keep down the peak. On the other hand, with a private generating station, it would be cheaper to fit a flywheel to the generator and to design the latter with good inherent regulation, so that it could take the short peak load with only a comparatively small drop in speed and voltage. It was to a great extent, the flywheel in the Ilgner system that levelled the peak but it might be less costly to put this flywheel on the steam generator than on a separate motor generator, and practically the same result, of keeping down the size of the generating plant, was obtained.

Mr. R. LIVINGSTONE (communicated) agreed with the author as to the efficiency and ease of operation of the induction motor drive comparing favourably with regenerative systems having the Ward-Leonard control. The efficiency of the winding gear varied from 60 to 80 per cent., and the efficiency of the electrical gear between winding drum and power mains varied from 55 to 70 per cent. when a motor-generator set was used, so that the resulting overall efficiency was only 33 to 56 per cent. With good acceleration and moderately long winds this efficiency could be obtained with the single induction motor drive in spite of the large rheostat losses during acceleration and retardation. Gearing, however, was essential between the induction motor and the winding drum, if a motor having a good power factor and efficiency was used, since the winding drum could not be run at more than 120 revs. per min. for short winds of small power, and 65 revs. per min. for long winds of large power. An induction motor speed of 375 revs. per min. was consistent with good economy up to very large sizes (200 H.P.), but the necessary gearing might be a source of trouble. A common source of trouble in induction motor drives of winding drums or rolling mills was the slip regulator, and the most feasible scheme seemed to be the moving of the liquid in the resistance by means of powerful pumps rather than to move the plates of motors. High rates of acceleration were necessary if induction motors were to be economically used, but there was a point where increased capital cost of motor and gearing outweighed saving in current. He thought that best rates of acceleration would not vary considerably and would be 3 ft. to 5 ft. per second per second with current at ½d. to 1d. per unit. The connection of large winding plant direct to supply mains would necessitate in many cases a flywheel equaliser, and this would be a serious limit to the direct drive by induction motors. The author adhered to braking by means of the motor, but it was a question whether it would not be possible to design a mechanical brake with a suitable cooling device to absorb the energy lost in retardation.

Messrs. J. C. MACFARLANE and H. BURGE (communicated) thought t

Digitized by Google

author had made the best of a bad case. They took exception to the assumption that the direct induction motor drive for winding engines was necessarily less costly than a converter system, and also that it was easy to get rid of the large amount of rheostatic waste energy. They put forward the following reasons why the converter system was preferred: Firstly, the current demand from the mains during acceleration was only one-third of that with the induction motor drive; secondly, the control was simpler; thirdly, regeneration was possible; fourthly, the efficiency was higher; and, lastly, these advantages were obtained with practically no addition to cost. They then described a system which they considered had many advantages over both the Ward-Leonard and induction motor drive. In this the three-phase supply was converted to direct current at variable voltage by a special motor generator. The direct current winding motor was shunt-wound with variable field strength arranged to be about twice as great at starting as at full speed. Two similar direct-current machines were also coupled together, the armature of the first being tapped to slip-rings connected to the supply, whilst the excitation of the second was supplied from the first and varied between a positive and negative maximum by a reversing field regulator. Each of these machines dealt with approximately half the power. The power demand was approximately constant and the power factor practically unity. The capital cost for a particular case (300 H.P. average power) was as follows: Induction motor drive £700, Ward-Leonard £850, proposed converter £650.

Mr. W. H. PATCHELL said doubtless the author would reply in the "Journal" to all the points raised, so he did not propose personally to deal with them. Mr. Heather when he prepared his Paper had the courage of his convictions, since he had many plants on order at that time. Personally he thought the question of whether the Ward-Leonard or the induction motor system should be adopted depended primarily upon where the current would be obtained. If a private generating station was to be erected they would not want to instal plant to supply the demand of a large winder driven by an induction motor; whereas the position might be reversed if a supply of power were available from a large station. Mr. Heather, of course, dealt with the subject from his point of view in South Africa, where large power stations were available, and he was able to buy current at a cheap rate. In a letter to the speaker Mr. Heather said his first Ward-Leonard winder was working well, and the power company viewed the winder with equanimity. In stage winding Mr. Patchell thought the direct coupled induction motor undoubtedly presented an immense advantage as regards space occupied if the supply company were prepared to stand the variations of load. Mr. Heather had mentioned the facility with which a winder attendant could be changed from steam to electric operation where the induction motor system was adopted. The preference the men taken off steam driving had for the electric winder was now quite common. The objection to balance ropes was chiefly the swing of the ropes. This swing was very great with a steam winder, but with an electric winder there was no swing at all, so that mining engineers would doubtless now appreciate the advantage of the balance rope. Replying to Mr. Gadsby, the diameter of the rope drum was 16 ft. and the maximum rope speed 63 ft. per second. The winder illustrated was working on a shaft of 516 yds. deep, and the useful load was 3 tons. The output was 1,800 tons per day, or about 200 tons per hour on the nine-hour day rating.

CORONATION EXHIBITION, SHEPHERD'S BUSH.

Notwithstanding that London will this summer be exceptionally well provided for in the way of exhibitions, the Coronation Exhibition at Shepherd's Bush, which was opened yesterday by H.R.H. Prince Arthur of Connaught, is likely to prove at least as popular as its predecessors. Although we hope at a later date to deal in detail with the exhibits of engineering and scientific interest, mention may now be made of the series of scientific exhibits. Judging from a preliminary inspection which, by the courtesy of the Exhibition authorities, we were able to make on Wednesday, it is evident that the science section will on the present occasion be a much more prominent feature of the Exhibition than in previous years. Much more space has certainly been devoted to this section, which comprises in addition to astronomy, meteorology, mathematics, chemistry and geology, &c., optics, mechanics, heat, physics, telegraphy and telephony. In each of these divisions there is an excellent collection of apparatus, and a feature is, for the first time, to be made of demonstrations and of apparatus in actual use. To indicate the extent to which this will be possible we may mention that two dark rooms are being constructed, one of which will be devoted to optical demonstrations, such as stroboscopic methods of measuring the speed of revolving shafts, whilst the second will be employed for demonstrating phenomena in connection with vacuum tubes and also X-ray work.

In the Mechanics division, we noticed Prof. Schwartz' machine for testing indiarubber; this apparatus will be shown in use. An apparatus to illustrate the small negative coefficient of expansion of invar is also being fitted up, whilst Dr. Shaw's electric micrometer will bring home to the general public the method by which measurements of the highest degree of accuracy can be obtained. A number of engineering models have also been lent for exhibition purposes, including some to illustrate alternating-current theory.

In the Heat division we may draw attention to the fact that two electric resistance furnaces will be shown; one by the Cambridge Scientific Instruments Co. will be used in connection with resistance thermometry and the Whipple indicator and various Féry radiation pyrometers, whilst the second, by Mr. R. W. Paul, will enable demonstrations to be made with his thermo-electric pyrometers and "unipivot" instruments.

In the Physics section, which has been organised by Dr. C. V. Drysdale, are included models illustrating the evolution of Lodge's rectifier valves for agriculture and X-ray work, and models by Messrs. Cossor showing the evolution of X-ray tubes. Among the instruments shown may also be mentioned universal shunts, woven wire resistances, vibration galvanometers, mutual inductance standards, a number of well-known Ayrton-Mather instruments, Dr. Drysdale's polyphase wattmeter, alternate current potentiometer, apparatus for measuring permeability, &c., &c. This last-mentioned apparatus is being exhibited by Mr. Tinsley, whilst other of the above-mentioned apparatus is being shown by Mr. R. W. Paul. Prof. T. Mather, F.R.S., has also loaned certain apparatus.

A special effort has been made to obtain a representative display of telegraphic and telephonic apparatus illustrative both of research and practice. The centre of interest is almost certain to be the Marconi transmitting and receiving stations, which visitors will be able to inspect whilst in operation; indeed, they will be permitted to send and receive messages between the two stations.

Mr. Tinsley shows a syphon recorder working on an artificial Atlantic cable, to illustrate various effects experienced in the transmission of telegraphic messages. Messrs. Burgess & Joly have arranged experiments to show the analysis of Morse signals, whilst Mr. B. S. Cohen exhibits apparatus in connection with telephonic transmission. Dr. Fleming has apparatus to illustrate the evolution of his cymometer; and finally we may mention Dr. Drysdale's vacuum tube experiments in connection with Messrs. Cossor to show the transmission of impulses along a helix.

In the above brief *resumé* it has been possible to do little more than indicate a small part of the multitude of apparatus to be found in the Science section, but sufficient has been said to show that visitors to the Exhibition will find in this section sufficient to occupy their attention for many hours.

As regards other sections, we must deal with these on a future occasion, but we may mention that the Education section promises to be of no little interest, and that the London County Council have a very interesting display. This includes one of their tramcars, a truck showing the arrangements of the gear, &c., and a most instructive collection of various ploughs, so that the whole method of operation of a tramcar is made clear, the ploughs being also shown in short sections of conduits.

At a luncheon given to the members of the Press on Wednesday last in the Banqueting Hall, on the occasion of the Press view of the Exhibition, Lord Blyth (vice-president and chairman of the Executive Council) presided over a large gathering. The toast of "Success to the Coronation Exhibition" was entrusted to Lord Rotherham, who made a very humorous speech, Mr. Kiralfy responding.

STATE CONTROL OF TELEPHONES.

On the 9th inst. the Postmaster-General received a deputation from the Liverpool Cotton Association on the subject of the future administration of the telephone service.

The deputation was introduced by Mr. Leslie Scott, K.C., M.P., and the Postmaster-General was accompanied by Capt. Norton, M.P., Sir Matthew Nathan and Mr. A. M. Ogilvie.

The POSTMASTER-GENERAL, in his remarks, said the number of telephone users was at present disproportionate to what it should be, and he looked to its being multiplied three or four-fold. The Post Office and its technical officers had been giving the most minute attention to every problem that could present itself in that connection. With respect to the suggestion that the telephone in the hands of the State might be starved, he said there had never been any difficulty in the provision of capital for the telegraphs, and they had already spent £11,000,000 on telephones also. The trunk service had been immensely developed. He should ask power in the Telephone Bill this year to raise several millions more (apart from the sum to be paid to the Company) for immediate development. He could not agree to the suggestion for a Telephone Committee or Telephone Authority, which could not get capital on easier terms than the Government.

As to the telegraph service, they could easily make the telegraphs pay by ceasing to provide telegraphic facilities in rural districts and by abolishing 6d. telegrams. The assertion that the Post Office was proved

Digitized by Google

to be inefficient by the fact that it made a loss of £1,000,000 a year on the telegraphs was contradicted by the earning of a profit of £5,000,000 a year on the postal side. If the Telephone Authority were to take over the telegraphs as well as the telephones it would have to bear the million a year loss which was now paid out of the profit on the postal service. Telephony was a most expert business and highly technical, and on technical questions the suggested Committee or Authority, which would not, presumably, be a technical body, could not give an opinion which would be worth having. As to rates, they suggested that the Postmaster-General would be pressed by the House of Commons to reduce rates, and then they would have the loss on the telegrams repeated. There was a movement among Chambers of Commerce and similar bodies to retain the unremunerative flat rate, with the result that so far as the large user was concerned the telephone service would be run at a loss. There would always be pressure to reduce rates, and it would be the business of the Postmaster-General to prevent rates being put at such a point as would be unremunerative. He suggested that he should have the advice, unless the table of rates to be proposed by the Post Office was generally accepted, of a committee consisting largely of commercial men, who should go into the question of rates after the sum payable to the National Telephone Co. for their plant had been ascertained. The wishes of the deputation to that extent would be met, but a standing committee was a different matter. An Advisory Committee would have to rely as much on the highly efficient technical officers on the engineering side, on the traffic side, and on the staff side as the Postmaster-General had to do.

LONDON'S TRANSPORT FACILITIES.

Before a meeting of the City of London Tradesmen's Club, at St. Bride's Institute, London, on Thursday last week, Mr. A. W. Gattie opened a discussion on this subject.

Mr. GATTIE prefaced his remarks by a reference to the Paper which he read before the Royal Society of Arts on May 3 (and which was fully reported in THE ELECTRICIAN). He referred briefly to the building it is proposed to erect, and its approaches by road and rail, and said it was proposed to give a demonstration of the apparatus at Coventry a few weeks hence. A Royal Commission was appointed to deal with the street-traffic problem some eight years ago, and advised the expenditure of what he described as a preposterous amount of money on street widening. But nothing had been done. Recently the Board of Trade issued a Blue Book, again advising a lavish expenditure of money on street widening, but carefully avoiding the congested central area. There was a business remedy for the difficulty. Widening streets to allow further opportunities for the loitering of vans was an act of folly. We had also the highest freight rates in the world, impassable streets and railway companies paying either a paltry dividend or none at all. The core of the trouble was the slow-going, loitering or stationary van. The best results were to be obtained by putting the centre of distribution in the heart of the busy area. Mr. James Swinburne and Sir Wm. Preece raised no doubt as to the proposed apparatus being able to perform the work he (Mr. Gattie) claimed it would perform.

Mr. ALLAN RAMSAY (secretary of the club) supported Mr. Gattie's scheme heartily, and hoped it would prove a successful attempt to deal with the City-traffic problem.

Mr. JOB MORRIS referred to a scheme he prepared some years ago for carrying goods underground. That scheme was practically adopted by the London County Council in their tunnel under Kingsway, only they utilised it for passengers instead of for goods. Such a scheme as Mr. Gattie's, to be made perfect, must be adopted in its entirety. If the millions that had been spent on tubes for passengers had been spent on such a scheme as this the railways would have been available for passengers. He supported Mr. Gattie's scheme.

In reply to Mr. Geo. Alexander, Mr. GATTIE said it was not proposed to compensate the 800 firms of carriers, forwarding agents and carmen, but they could take shares in the New Transport Co.

Mr. PARKER referred to the chaos which existed at Billingsgate, and wished success to any scheme which could bring order out of it.

Mr. BURTT said it was absurd to send passengers underground and let the roads be occupied by waggons. The proposals for street widening were wicked. It seemed to say: "There is a lot of badly organised traffic, but go as you please and we will give you more room to go as you please."

Councillor THOS. DARRINGTON said Mr. Gattie's idea was an interesting and fascinating one, and they were to be congratulated upon having a gentleman with such a thorough knowledge of the subject to come and stimulate them upon it.

In reply to Mr. Chris. Robinson, Mr. GATTIE said the Clearing House and its cars could deal with the Smithfield meat trade more expeditiously than the vans at present used, but there would be no interference with the work of the markets. The Clearing House could unload a meat train as easily as a fish train. Mr. Cornell, the meat carrier, approved of the scheme.

In reply to Mr. WOOLLVEN, who asked as to the handling of perishable goods, Mr. GATTIE said the Clearing House could deal with 2,000 5-cwt. bales a minute and shunt 170 loads in 10 minutes. The New Transport Co. would be pleased to co-operate with the carriers. The rules for working the company's scheme would be made by the Board of Trade.

A resolution that "after hearing Mr. Gattie on the proposed scheme of a general Clearing House, the club endorses the principle and would support an inquiry by the Corporation of London" was carried unanimously, and a vote of thanks to Mr. Gattie was approved.

THE INSTITUTION OF ELECTRICAL ENGINEERS, BENEVOLENT FUND.

The thirteenth annual general meeting of the contributors to this fund will be held at the offices of the Institution of Electrical Engineers, Victoria-embankment, London, W.C., on Friday, May 26, 1911, at 4 p.m. The statement of accounts to December 31 last shows that the capital of the fund stands at £3,700 invested with the exception of £23. 11s. 6d. in cash. The income for the year is made up of annual subscriptions £95. 13s. 8d., donations £49. 3s. 2d., dividends and interest £120. 10s. 9d., balance as per last account £203. 15s. 11d., total £469. 3s. 6d Expenditure: Grants £51, transferred to capital £200, postages, &c., £2. 17s. 3d., balance down (cash) £215. 6s. 3d. The balance-sheet shows assets: Capital £3.700, from income account £215. 6s. 3d., sundry creditors £1. 11s., total £2,916. 17s-3d.

PARLIAMENTARY INTELLIGENCE.

BRIGHTON, HOVE & DISTRICT RAIL-LESS TRACTION BILL.

On Friday this bill came before a House of Lords Committee, presided over by the Duke of Bedford.

Mr. WEDDERBURN, K.C., for the promoters (the Brighton & Hove Omnibus Co.), said that power was sought to run rail-less cars along the cliffs between Ovingdean and Rottingdean, near Brighton, a distance of 2½ miles. Brighton Corporation opposed on the ground that they supplied water to Rottingdean, and there was danger of damage to the mains by reason of the weight of the cars. Every other local authority concerned supported the bill.

Mr. TALBOT, on behalf of the Corporation, claimed a right to be heard against the bill until it was amended to protect the interests of the Corporation. Parliamentary authority to sanction rail-less traction had hitherto been given only when it was an adjunct to existing tramways.

The Committee decided that the Corporation opposition should be limited to the clause relating to agreements with local authorities as to the supply of electrical energy. The bill might proceed.

MATLOCK DISTRICT RAIL-LESS TRACTION BILL.

On Friday the House of Lords Committee (presided over by the Duke of Bedford) rejected this bill.

Mr. ROBT. HAMMOND, who gave evidence on behalf of Matlock Bath Council (in oppositon to the bill) said the promoters had not made sufficient provision in the estimates for construction and working. Given proper care the system was safe, but if by any chance the "live" and "dead" wires "reversed" there would be danger to the public. The Committee gave no reason for their decision, but it is understood that they were influenced chiefly by the opposition of the local authorities and the alleged unsuitability of the roads for the working of the system.

As a result of the decision the promoters of a similar scheme for the Malvern district withdrew their bill.

ABERDARE URBAN DISTRICT COUNCIL BILL.

A House of Lords Committee (presided over by the Duke of Bedford) commenced on Monday the consideration of this Bill.

Mr. WEDDERBURN, K.C., for the promoters, said the object of the bill was to construct ordinary electric tramways (supplemented by rail-less traction), to make street improvements, &c. £47,000 was the estimated cost of the tramways. There was great necessity for tramways at Aberdare. The working of the tramways would, it was believed, result in profit. The proposal was to have a line of tramways about 2½ miles long with four rail-less routes running from the main line. Glamorgan County Council opposed chiefly because for ¾ mile one rail-less route would go over one of their narrow roads. Counsel denied that any danger would be caused. The opposition of the Taff Vale Co. was competition which, he said, Parliament did not listen in these days), danger in crossing their line, interference with signalling, and the probable necessity of the company having to pay rates in aid owing to the tramway not paying.

Mr. STEPHEN SELLON, engineer to the scheme, said Aberdare was a good field for tramway enterprise. There were no engineering difficulties. He had gone into the financial position, and came to the conclusion that the lines would yield a substantial profit. His estimate of the total cost of the tramways was £33,180, and the capital cost of providing the overhead equipment, cable and cars in respect of the rail-less traction £13. The question of level crossings over railways by tramways was provided for under the Tramways Act, 1870. As to the rail-less traction it was anticipated that about 1d. per passenger would be secured. The fare by rail-less trolley cars was proposed to be exactly the same as the tramcars.

Mr. J. B. HAMILTON (general manager of Leeds City tramways) supported the rail-less portion of the scheme, which he considered would be found to be a profitable undertaking when run in conjunction with tramways. Rail-less traction was admirably adapted to the needs of a town like Aberdare.

Mr. I. E. WINSLOW, consulting engineer and Mr. O WILLIAMS, surveyor to Aberdare Council, also gave evidence.

For the Taff Vale Railway Co. the manager (Mr. Beasley) and Mr. Hammond gave evidence in opposition to the tramway scheme.

Yesterday (Thursday) the Committee passed the tramway and rail-less trolley clauses.

LONDON TELEPHONE EXCHANGES.

In the House of Commons on Tuesday, Mr. Astor asked the Postmaster-General whether the National Telephone Co. were refusing to connect applicants to the Gerrard Exchange, and whether the Post Office was refusing to connect applicants to the Mayfair Exchange.

Mr. H. SAMUEL said he understood the existing equipment of the National Company's Gerrard exchange was working at its full capacity; and the same was practically true of the Post Office Mayfair exchange. New apparatus was, however, being added at Mayfair to provide accommodation for additional subscribers, and was expected to be ready next month. As soon as the Gerrard exchange came into his hands, steps would be taken to provide additional accommodation there also. The Company stated that they are unable to undertake any extension at present.

METROPOLITAN ELECTRIC TRAMWAYS BILL.

On Wednesday a Select Committee of the House of Commons, presided over by Sir Luke White, passed the preamble of this Bill, the main objects of which are to reconstruct a bridge over the river Lea, and to construct additional tramways on the Middlesex side, &c. Essex County Council have undertaken the work of reconstructing the bridge and Middlesex County Council will construct the tramways which will run over the bridge and link up with the Walthamstow system. Tottenham Urban Council opposed the clause in the Bill which took away from them the right to purchase the tramways constructed in their area, but the Committee decided that the clause should remain.

PURCHASE OF LOTS-ROAD POWER STATION.

On Tuesday a House of Lords Committee passed this bill of the Metropolitan District and London Electric Railway Co.s for the transfer of Lots-road power station from the Underground Electric Railways of London to a joint committee of the two companies.

GREATER LONDON RAILWAY BILL.

The Select Committee of the House of Commons, presided over by Sir J. Compton-Rickett has continued the consideration of this Bill this week and has taken much evidence in support of its provisions.

NEWCASTLE-ON-TYNE CORPORATION BILL.

The tramway clauses of this Bill, which is being considered by a House of Commons Committee, were dealt with on Tuesday and Wednesday.

The tramways manager (Mr. E. HATTON) stated that the total cost of the proposed line from Scotswood to Throckley was £40,248. Eight cars would be provided for at a cost of £5,200, giving a 10 minutes' service morning and night and on Saturdays, and a 15 minutes' service in the day.

The North-Eastern Rly. Co. opposed on the ground of competition.

After hearing the evidence, the Chairman (Mr. Helme) announced that the preamble, so far as it concerned the tramways, was proved; but in regard to the two proposed rail-less trolley routes the preamble had not been proved.

L.C.C. TRAMWAYS AND IMPROVEMENTS BILL.

A Select Committee of the House of Commons (presided over by Sir Luke White) has further considered this Bill during the week. The proposed tramways from the Marble Arch to Cricklewood, via the Edgware-road, was withdrawn.

Oldham & Saddleworth District Rail-less Traction Bill.—The promoters of this bill have notified that they do not intend to proceed further with the measure.

LEGAL INTELLIGENCE.

National Telephone Co. v. the Postmaster-General.

The Railway Commissioners (Mr. Justice A. T. Lawrence, the Hon. Sir E. Cecil Duthie-Hardy and Sir James Woodhouse) have continued the hearing of the application of the National Telephone Co. for a declaration that the terms of the agreement under which the lands, plant, &c., of the company are to be taken over by the Post Office are to be construed in a wider and more liberal spirit than that now stated to be adopted by the Postmaster-General.

Sir Alfred Cripps, K.C., Mr. Danckwerts, K.C., Mr. Morten, K.C., Mr. Rose Lankester, K.C., and Mr. Gaine appeared for the applicants; the Attorney-General, the Solicitor-General and Mr. Branson represented the Postmaster-General.

At the close of the proceedings on Friday it was pointed out that it was of the utmost importance that the arbitration should be practically concluded before Aug. 1, 1911, as in the event of its being decided that the Postmaster-General was entitled to reject all duplicate exchanges it would require considerable time for Post Office exchanges to be adapted to the additional work required of them.

The Solicitor-General (Sir JOHN SIMON, K.C.) contended that in competitive areas the Government Department was bound to take over only such plant, &c., as was necessary for its "actual requirements" at the time of the transfer; while in non-competitive areas—that is, where the National Company alone had a service—the Government would feel bound to take over also plant and equipment reasonably provided for the extension of the service.

Mr. Justice LAWRENCE: If it is a fair bargain in non-competitive areas, why should it not be held a fair bargain in competitive areas?

The SOLICITOR-GENERAL: Because I have already provided myself in the competitive areas. It was (he continued) matter of common knowledge that the average use of the telephone in London is low, compared with cities on the Continent and elsewhere, and that a great increase may be anticipated. For that he had allowed in the competitive areas by making provision for the service of the whole of the population. But in a non-competitive area no such question arose. There the Department had to make provision for the plant provided by the company, and of that plant he only claimed the right to reject such as did not reach a specification set up by the Department.

Sir ALFRED CRIPPS said the obligation of the Postmaster-General was to buy "all plant, land and buildings . . . in use by the company on Dec. 31, 1911," subject only to the exception that plant not constructed in accordance with the prescribed regulations might be rejected, as might also be the plant in competitive areas which the P.M.G. should consider not to be suitable for the service he was giving on Dec. 31, 1911—that was to say, in the competitive areas it was possible the company might be working on one system and the Post Office on another. That contingency had been foreseen and consistently provided for throughout the 1905 agreement. If it had been intended to reject the whole of a duplicate system it would have been perfectly easy to have so agreed. There was nothing which required the word "suitable" to be changed into "necessary."

On Monday Sir ALEX. KENNEDY gave evidence on behalf of the company, and explained the working of the telephone service by means of photographs, instruments and models. He said the magneto machine was one of the earliest devices in telephones. Under that practice there was a subscriber's battery. Under the more modern system there was a central battery at the exchange. Witness himself approved of the local battery system, just as he preferred the hand microphone. He could not approve, he said, of the central battery system as established by the Post Office. The most expensive part of a telephone system was, naturally, the cables, &c., which would, in ordinary cases, account for two-thirds of the whole cost of construction. Telephone engineers had not so much to do with the conductivity of the wires as with their capacity for transmitting sounds, which was another and much more complex matter, and was at the bottom of all the schemes of telephonic circuitsand the ascertainment and photography of sound waves. He thought that was the great difficulty in the P.O. system. They had a great system of trunk wires, and in order to improve the audibility over long distances they had put up overhead wires. Sir Alexander gave evidence of the relative merits of insulating materials, and, after explaining the respective merits of gutta-percha and indiarubber, gave his opinion in favour of a dry paper sheathing. He thought the two former substances of very inferior value where high-frequency currents were employed. Besides the local battery system and the central battery system, witness said there was the automatic system. By the automatic system a subscriber could call up any other subscriber without the intervention of the exchange. Witness expressed his own opinion in favour of the local battery system. He understood there were 21 out of 63 exchanges belonging to the National Company within the London area which had been rejected by the Postmaster-General. He was given to understand that all their 21 rejected stations were fitted with the local battery system, and that formed one of the grounds of their rejection by the Postmaster-General. He believed a central battery might be preferable for large exchanges, but he did not think it was at all recognised that they were the best for small exchanges. Purley was an example of the small new exchanges in which the central system had not been adopted.

Major W. A. J. O'MEARA, C.M.G., engineer-in-chief of the Post Office, said that under the Post Office system there was no reason why two subscribers on a private wire should ever have their communications pass through an exchange at all, and it was a more economical system for the subscriber. Direct communication could be established through what might be called a "sorting frame." With the aid of certain apparatus set up in Court witness gave a demonstration of how those private wires should communicate without passing through an exchange.

Replying to questions by Sir Alfred Cripps, Major O'Meara gave examples of how, by the magneto system, it might be difficult or impossible for the person at the exchange to say when one or the other of the persons communicating over the wire had rung off, which would not be possible under the Post Office system.

Sir Alfred Cripps asked if the private wires were not always tested in the exchange, to which the witness replied that it was not so, as a matter of fact.

Sir ALFRED CRIPPS: But if the wires were laid into your exchange you would test them there?

WITNESS: If they were there they would naturally be tested. Witness further stated that the Post Office expected to take over 100 private wires working through the City and central exchanges, through which about 19,000 wires passed.

Major O'MEARA was further cross-examined in order to show that many of the clauses in the notices of rejection given by the Government

Digitized by Google

to the company conflicted with each other. Witness said he believed Southall and Purley were the only two exchanges that had been established since 1907. A number of questions were put as to the definition of the "equipment" of an exchange.

Sir ALFRED CRIPPS: Is everything that you find in an exchange, apart from the wires, part of the equipment?—At a certain point a cable comes into the exchange, that cable has to be attached to some structure, and that structure and everything inward is a part of the equipment.

Mr. Justice LAWRENCE: And when you say "equipment" you mean to use it in the wider sense of the machinery necessary to communicate along the system?—Yes.

Sir ALFRED CRIPPS: You make a distinction between iron wires in competitive and iron wires in non-competitive areas. In the one case you say "wires forming part of any telegraphic lines," in the other you say "iron wires forming part of any telegraphic circuit"?—Yes, the iron wires carrying a current in any telegraphic circuit.

Are there not numerous iron wires which are not part of a telephonic circuit?—That may be so. The transformer has iron wires around it, and these are not iron wires in the sense of carrying the current as part of the circuit.

Mr. Justice LAWRENCE: Is iron wire used in a telegraphic line which is not part of the circuit?—Yes.

Sir ALFRED CRIPPS: Do you suggest that iron wires used for the purposes of attachment, as stay wires, &c., should be rejected?—Yes, if the line is rejected.

Mr. Justice LAWRENCE: Let me ask whether a distinction is drawn between iron wire forming part of a telephonic line in the competitive area and iron wire forming part of a telephonic circuit in a non-competitive area?—Iron wire is objected to when it forms part of a circuit and the line is part of the circuit.

His LORDSHIP: So far as I can see, your only objection would be to iron wire forming a part of the circuit?—Forming part of the conducting circuit. It does not refer to that which is used mechanically.

Counsel then referred to the clause in the notice of rejection given by the Post Office to the company which specifies "all instruments, wires and apparatus which fail to satisfy the tests of audibility" specified in the agreement, and asked: If a particular wire did not satisfy the test of audibility, that would be a question of finding out the fault and setting it right?—It might or it might not.

With reference to another notice of rejection in the case of wires carried over an electric railway, Major O'Meara said that would only refer to the section of the line crossing the railway, but all lines carried along an electric railway in such a manner as to afford any danger of contact would be rejected. The portion of the line which was not rejected would be retained. In respect to lines along electric railways, witness said that whether they were overhead or underground they were subject to the notice of rejection. The Post Office itself, he said, had dispensed with all its lines along electric railways and subways in which electricity was used. The notice did not apply only to electric railways; it was given on the ground of want of access.

Sir ALFRED CRIPPS: In your notice you say you exclude "all plant not constructed in accordance with the specification and rules," but the agreement allows for the bringing of such plant under the consideration of the valuation tribunal. How are you going to do that if you start by ruling all such plant out?—If the plant has not been constructed in accordance with the rules and specifications then there is the notice to exclude it.

Have you taken any steps to ascertain what plant, if any, has been so constructed?—I think that is an impossible task at the present time.

Do you mean that you have taken no steps to ascertain whether any of the Telephone Company's plant will come within this objection?—You have already told the Court the number of officers engaged in carrying out this process. It is quite impossible to get any idea of what plant is in existence in the way you suggest.

His LORDSHIP: Does it come to this, then, that the notice is given by way of precaution in case any of the plant should not be constructed in accordance with the rules and specification?—Quite so; it identifies the class of article. The matter had to be decided by June 30.

His LORDSHIP: But you cannot decide until you know what it is you have to come to a decision upon.

WITNESS submitted that that was a matter for the Court.

In re-examination, Witness said that the reason of the objection taken to telephone wires across or along railways which were worked by electric power was that the wires were liable to come into contact with the railway cables which carried dangerous current, and persons using the telephone wire might receive a dangerous shock. Careless workmen, for instance, on an electric railway might easily cause a contact between the live rail or wire and the telephone wire with dangerous results.

In answer to his LORDSHIP, Witness said there had been an increase of 80 per cent. in the development of the London Post Office telephone service since 1902. Since 1905 the number of stations had increased 43 per cent.

Sir JAMES WOODHOUSE: The National Company, I suppose, has developed at an even greater ratio?

Sir ALFRED CRIPPS: It has doubled in the last eight years.

In answer to further questions by his LORDSHIP, Witness said that when the Post Office decided to take up any portion of their line in the case of underground cables, the cable would be taken up and sold for market value, but it was found to be cheaper to leave the disused conduit in the ground. In the case of the overhead wire, the poles would be taken down, and, if nearly new, would be used in connection with some other part of the system; but if the poles were old they would be sold on the ground for what they would fetch. In the case of iron wire (which would only be used in telegraphic work), if it were too old, it would be buried at the spot where it was taken down, but where it was worth it, or in the case of copper and bronze wire, it was sold for its market value. It was seldom worth while to use the wire again.

Sir RUFUS ISAACS then opened his argument upon the contention of applicants that the notices of objection were invalid. What was contemplated, he said, was that when a notice was given the Court should pronounce an opinion on it.

His LORDSHIP: But if the notice given is so bad that the Court cannot pronounce upon it, what are we to do?

The ATTORNEY-GENERAL: The contention here is that the notice does not sufficiently identify, that it is too vague and not comprehensive. I submit that the notice given is sufficient to be understood by persons dealing with the same subject-matter, and they would know to what particular class the notice referred. Of course, if the Court thought some limiting words should be inserted, it had the power to do so.

Sir ALFRED CRIPPS, replying on behalf of the National Co., said if the arrangement were that the property of the Company was to be taken over on "tramway" terms, then all classes would be included prima facie. But there was introduced a procedure under which the Post Office claimed to exclude certain classes of property from the valuation, and it was to make provision for that that the agreement was made. The notices of exceptions given by the Post Office should show what the particular items of plant, &c., were which they claimed to have excluded from the inventory. It was not sufficient for the Postmaster-General to say that the matter was difficult. In substance the Postmaster-General was trying to throw on the National Co. the onus of clearing up that extremely difficult question by saying what was or was not specified for rejection in the notices. On the contrary, the Postmaster-General ought to specifically declare what he would or would not accept. There were three questions by which these notices must be tested: (1) Do they give the National Telephone Co. the information to which it is entitled? (2) Do they give the valuer the notice to which he is entitled? (3) Do they give this court the information to which it is entitled? In none of these matters could the validity of the notices be sustained. The question had been practically discussed as a whole upon the notice referring to the London area which was by far the largest and most important. Any matter at issue in respect of the other areas was capable of adjustment. He argued that the notice was bad, as a whole, but, alternatively, he said that, if the Commission was against him on that point they might decide that it was bad in particular parts.

The Commissioners intimated that they would visit the Avenue and Gerrard (London) exchanges to make a practical examination of the effect of the agreement and notices of rejection.

Yesterday (Thursday) the ATTORNEY-GENERAL submitted that the notice of exception was sufficient if it defined classes of material to be rejected.

Mr. Justice LAWRENCE: Is it sufficient to say you will take over all except such as have some defect?

COUNSEL said he did not think that any engineer could have any difficulty in deciding the subjects to which objection was taken. He submitted that there was nothing to prevent the Court from saying that the effect of any paragraph was to be limited. He agreed that the Court could not amend the notice of objection by extending it, but it was a fallacy to say that they could not limit the scope of the objection. He submitted that the notice No. 2 (dealing with particular localities and exchange areas) was sufficiently specific to indicate, not only the locality but also the character of the things objected to.

Mr. Justice LAWRENCE intimated that the Commission would deliver its judgment on the subject as soon as possible.

Johannesburg Municipal Council v. D. Stewart & Co. (1902) (Ltd.

In the Court of Session, Edinburgh, on Saturday, Lord Ormidale heard counsel on a motion by defendants to adjourn the proof in this action for the recovery of £400,000 damages for alleged breach of contract in connection with the supply of gas plant for generating electricity.

Mr. MORISON, K.C., for plaintiffs, said defendants had recovered 12,000 documents, only a small proportion of which had any bearing on the abandonment of the contract. Delay would involve his clients in great hardship and serious expense. Several witnesses were on their way to this country, and his clients had had to make considerable readjustments of staff to allow their officials to get away.

Mr. MURRAY, K.C., for defendants, denied that the motion was made purely for delay. A special staff of ten or a dozen typists had been engaged upon the productions since the middle of February, and had not yet completed their task, and he was told that, so far as counsel were concerned, it would take a fortnight to even read the papers.

Mr. CLYDE, K.C., for plaintiffs, said defendants had £143,095 of plaintiffs' money in their pockets. If plaintiffs were right, that money would have to be paid back to them, and plaintiffs were apprehensive of delay. If defendants put the £143,095 on the table of the court, they could have their delay, but he opposed the motion on any other conditions.

His LORDSHIP granted the motion, subject to the right of plaintiffs to recover any expenses which the delay entailed. Leave to reclaim was granted.

Hastings & District Electric Tramways Co. (Ltd.)—On Tuesday Mr. Justice Neville granted the petition for the reduction of capital from £500,000 to £372,942. 10s.

Digitized by Google

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Amalgamated Society of Engineers.—The 60th annual report (for 1910) states that at the end of the year there were 110,733 members, an increase of 3,593 over 1909.

The income from all sources to the general fund was £422,797, against £399,406, increase £23,391. The contributions, fines and levies amounted to £390,649, compared with £370,756. The amount received from entrances was £3,262, an increase of £168, while interest from the fund was £19,195, a decrease of £2,472. The superannuation reserve fund started the year with an accumulated fund of £382,046, and finished with £415,858, an increase of £33,811, while the increase for 1909 was £32,114. The general secretary (Mr. Jenkin Jones) states that this "establishes beyond doubt the absolute security of an old age pension to our members." The combined value of the funds at the close of the year was an increase of £24,956. The cost for donation benefit was £92,067 less than in 1909, whilst the amount paid for contingent benefit was £3,221, compared with £3,211 for 1909. The amount spent in sick benefit was £9,061, £752 less than in 1909. £142,491 was paid for superannuation benefit, increase £5,694. The applications for benevolent grants were considerably less, and the total amount granted was £5,267, against £9,009 for 1909, but the branches abroad who levy themselves paid £282, so the actual amount granted by the council was £4,985.

In regard to the question of maintaining the Parliamentary contingent, the report states: "We are now relying on voluntary subscriptions from the members for the maintenance of our two members, and it is very regrettable to state that the amount of subscriptions received is not encouraging." As to the National Insurance Bill, the general secretary states "that at this moment very important legislation involving two schemes, which probably will require from the workmen 4d. per week for one scheme and 3d. per week for the other, and further contributions from the State and the employer, is proposed. The proposed schemes of the Government are new, but they are highly important, and may have adverse effect from the trade union point of view, and we shall be deeply disappointed, as it may mean another 7d. per week, which must come from the wage of the workman, and which unquestionably requires the watchful eye of the Labour Party and our friends to see that justice is done to the trade unions."

Arc Lamps on Approval.—Owing to the diversity in practice regarding the sending out of arc lamps on approval, and the letting out of arc lamps on hire and hire purchase, the National Electrical Manufacturers' Association have issued the following rules in the hope of producing uniformity in these matters:—

Conditions on which Arc Lamps are to be supplied on Approval or on Hire.

ARC LAMPS ON APPROVAL.

1. *Charge for the Use of the Lamps and Carbons.*—No charge is made for the use of lamps during the approval period, and each lamp will be provided with one trim of carbons. All further carbons used must be paid for.

2. *Use of the Apparatus.*—The lamps must be properly erected in accordance with our instructions and burnt with the carbons which we supply with them. No larger current or higher voltage must be used with the apparatus beyond that stated on the instructions sent with it or in the catalogue.

3. *Packing.*—The goods will be sent properly packed carriage paid to your address, and are to be returned properly packed in the same manner and in original case in which they were delivered, carriage paid to our works, together with an advice note within the time period agreed. Should they be detained longer, we shall be entitled to consider the lamps as definitely purchased by you.

4. *Damage to Lamps.*—The lamps when returned to our works will be inspected, and you will be notified within five days from receipt of the goods as to any breakages or repairs that are necessary, other than those due to fair wear and tear, and these are to be paid for at the usual rates.

5. *Insurance of Goods.*—From the time the lamps reach you to the time of their return to our works they are to be held in trust and insured against fire and theft by you.

ARC LAMPS ON HIRE

(Arc lamps on hire for electrical exhibitions are excluded).

1. *Carbons.*—All carbons supplied are to be paid for.

2. *Carriage.*—The total costs of freight and carriage from the works to the user and back again to be paid by the hirer.

3. *Packing.*—The goods to be sent properly packed by the maker, and also to be returned properly packed in the same manner in the cases in which they were despatched, carriage paid to the maker's works, a suitable advice note of despatch being sent.

4. *Damage.*—The lamps when returned to the maker will be inspected, and the hirer will be notified within five days from receipt of the goods as to any breakages or repairs that are necessary, other than fair wear and tear, and these are to be paid for at the usual rates.

5. *Use of the Apparatus.*—The lamps must be properly erected in accordance with instructions and burnt with the carbons which the makers recommend. No larger current nor higher voltage must be used with the apparatus beyond that stated on the instructions sent with it or in the catalogue.

6. *Loss or Damage of Goods.*—From the time the lamps reach the hirer to the time of their return to the maker they are held in trust by the hirer, who will be responsible for any loss or damage which may occur.

7. *Period of Hire.*—The period of hire shall be reckoned from the time the goods leave the maker to the date they are received by him.

8. *Wiring.*—The hiring prices do not include the cost of wiring for or fixing the lamps and resistances.

9. *Hire Purchase.*—These conditions do not apply to lamps supplied on signed hire-purchase agreements.

Barnes.—The L.G. Board have sanctioned the borrowing of £8,600 for additional generating plant.

Coronation Illuminations.—At *Birmingham* the Council House will be illuminated by the electricity department and the Town Hall by the gas department at Coronation time.—*Taunton* Council have sanctioned expenditure for the electrical illumination of the Municipal Buildings and Vivary Park on the evening of Coronation day.—*Norwich* Electricity Committee announce that they will supply current free for public or private illuminations on Coronation day and on the occasion of the King's visit and at ½d. per 8 c.p. lamp per night on other nights. The Castle, Municipal Buildings and Guildhall will be extensively illuminated.—*Southampton* Corporation are spending £200 on the illumination of the public buildings.—*Nelson* municipal electricity department will supply current at 2d. per unit for illumination purposes on Coronation day, the consumers also paying for the fixing of temporary meters.—*Blackburn* Council have decided to supply current free for Coronation illuminations, the devices for which are submitted by May 31 and approved by their electrical engineer.

Coventry.—At the meeting of the Electric Light Committee last week it was reported that the profit on the past year's working of the electricity department was £16,400.

The plant recently installed at the electricity works was officially inspected by members of the Council and others last week. The plant includes a 3,330 k.v.a. two-phase 50-cycle turbo-alternator, with direct-coupled exciter (by the British Thomson-Houston Co.), surface condensing plant, &c.

Electricity in Mining.—At the meeting of the Kent Coal Concessions (Ltd.) last week the chairman (Mr. Hy. A. Johnston) said that their parliamentary bill for obtaining a transfer of some of the statutory powers of the Kent Electric Power Co., and which would enable them to supply electric power to all their pits, was now unopposed. The first of the power stations was now in course of erection at Tilmanstone, and, according to guarantees, would be actually working by July 8. Those power stations would not only supply their own collieries—they were now indispensable to coal mining—but would attract manufacturers and provide them with cheap power, and enable their company probably to dispose of all their "small" coal.

Glasgow.—Last week the Corporation adopted the recommendation of the Special Sub-Committee on the improved light of the city that, with a view to ascertaining the relative lighting values of the proposed lamps, the pillars at present fitted with electric arc lamps in Argyle-street, Trongate, Sauchiehall-street, Renfield-street, Union-street and Jamaica-street be fitted with the new Metroflame arc lamp, and that an installation of high-pressure gas lighting be made in the streets surrounding the new Mitchell Library and St-Andrew's Halls, also in Granville-street, North-street, and Bath-street, at a cost of £475 for pillars and lamps.

Heckmondwike.—The adjourned inquiry into the application of the Council for permission to borrow £24,159 for the electricity undertaking was held last week. The inspector, Mr. H. R. Hooper, went carefully through the accounts of the undertaking, and evidence was given by the clerk, Mr. Macaulay, and the electrical engineer, Mr. G. H. Carter.

Ilkley.—The Council, who have been considering an electricity scheme prepared by Mr. J. W. Speight, have decided to send a deputation to interview the Board of Trade in reference to an application for a new provisional order.

Mr. Speight estimated the cost of the works at £6,324, but by using town gas instead of suction gas, and only laying distributing mains in the compulsory area, the expenditure would be reduced to £5,024. The annual expenses would be £967, and the first year receipts £1,013. 5s. 5d., leaving a net profit of £46.

Digitized by Google

Income Tax Reform League.—An interesting memorandum on "Wasting Assets and Income Tax" has been issued by this League, whose secretary and offices are Mr. G. O. Parsons, F.C.I.S., 25, Abchurch-lane, London, E.C.

Light Railways.—The Board of Trade have confirmed the Blackburn, Whalley and Padiham Light Railways (Revival and Extension of Time) Order, 1911.

Manchester.—At the meeting of the Council last week the annual estimates were submitted and adjusted, and the Electricity Committee suggested that they should hand over £19,496 in relief of rates.

Ald. GOLDSCHMIDT moved that this amount be increased to £24,500.

The Chairman (Mr. HOWARTH) said he did not see how it was possible to increase the amount. Unlike other Committees, they could not put off certain works.

The Committee's proposal was adopted.

The contribution of the Tramways Committee in relief of rates was then discussed.

Ald. GOLDSCHMIDT moved that the proposed contribution be increased by £10,000.

Ald. WILSON said a large sum of money would be required for improvements. If they handed over over all that money in relief of rates it would mean considerable delay in the development of their undertakings.

Mr. JOHNSON: I shall never be satisfied till the Tramways Committee give £100,000 in relief of rates.

Ald. BOWES, chairman of the Committee, said the Committee had always been very generous in their contributions. The question had been most carefully considered and they had come to the conclusion that they could not offer more than £75,000.

After further discussion this was increased to £85,000.

Mansfield.—An inquiry was held on Wednesday into the application of the Council for sanction to borrow £4,000 for extensions of the electricity undertaking.

Marylebone (London).—The charge made for fuse replacements is to be discontinued, except in special circumstances.

The general manager (Mr. A. Hugh Seabrook), in reporting upon the conversion of gas lamps to electricity states that the estimate for the work was £20,900, while the actual cost was £18,313. The estimated number of lamps to be converted was 1,385, the actual number being 1,371. The saving in cost against the estimate would have been greater had not local labour been employed, as the department started with £1,500 in hand by purchasing materials below the estimated figures.

Middleham (Yorks.)—A ratepayers' resolution has been passed in favour of public electric lighting. Two tenders have been received, one from a local trader for electric lighting (with 50 c.p. lamps), for £37 a year, the other from the Middleham Gas Co. (with 12-14 c.p. gas lamps), for £40. Current will also be supplied for private lighting.

Municipal Fire Insurance.—A ta meeting of Glasgow Corporation last week the recommendations of a committee appointed to consider the advisability of the Corporation creating a fire insurance department and taking all risks in regard to Corporation insurance against fire were adopted by 32 to 29 votes. During the discussion it was stated that in the last four years between £18,000 and £19,000 had been contributed to the insurance companies in fire premiums, while the fire claims did not exceed £500.

Municipal Telephony.—At the meeting of Hull Telephone Committee on Monday the manager (Mr. T. Holme) presented a report on the work of the department for the year ended March 31 last.

The gross receipts amounted to £12,550, an increase of £880 over 1909-10, and the gross profit (£5,026) showed an increase of £203. The total amount carried to loan repayment account was £6,976, to sinking fund £2,802 and to reserve (including last year's surplus of £1,323) £5,873, making a total of £15,651, or one-fourth of the capital outlay. The royalty paid to the Government last year was £1,258, bringing the total royalties to £6,224. Gross profit has increased from 6·3 per cent. in 1906 to 8·1 per cent. last year. The capital expenditure during the year was £1,186. The cost per station now stands at £19·95, compared with £20·58 last year, and was below the estimate of £20 given by Mr. A. R. Bennett at the L.G. Board inquiry. The scheme for 3,070 stations has been completed, with over £2,500 of the loans unexpended.

The report of the accountant (Mr. W. H. Smith) states that the ratable value increased from £225 to £723, an additional burden of £207. 15s. After meeting interest, repayment charges and income tax, the net profit was £1,168. 4s. 9d. The results were obtained with a flat rate of £5. 5s. (£5 for private houses).

Norwich.—On Tuesday a special Committee was appointed to consider and report upon the offer of the Norwich Electric Tramways Co. to sell their undertaking to the Corporation.

Presentations.—The directors and secretary of the Carmarthen Electric Light Supply Co. have presented their manager (Mr. Thomas d'Arcy Nassau) with a silver rose bowl on the occasion of his marriage.

Harrogate electricity staff have presented a gold watch to Mr. W. Firth, who is leaving for Australia.

Provisional Orders Revocation.—The Board of Trade have revoked the Newark Electric Lighting Order, 1900, and the Newark Electric Lighting (Amendment) Order, 1907, as from May 9.

Rotherham.—An unopposed inquiry was held on Tuesday into the Council's application for sanction to borrow £27,832 for extensions of the electricity undertaking.

Evidence was given by the Town Clerk and the Borough Electrical Engineer. The Town Clerk said there were 520 consumers and last year 2,669,727 units were sold. The capital expended was £58,310, of which £12,509 had been repaid. The gross revenue was £17,510, working expenses £9,665, interest £2,227, repayment of principal £1,880, net profit £3,740, renewals fund £12,153; total cost per unit sold 1·237d., average price per unit 1·573d. £2,000 of this year's profits had been applied in relief of rates.

South Shields.—An inquiry was held last week into the application of the Council for sanction to borrow £8,960 for extensions of the electricity undertaking.

Mr. FLEETWOOD PRITCHARD, for the Council, said that after what took place at the last inquiry, the borough electrical engineer (Mr. J. H. Cawthra) was instructed to consider whether it would not be advisable to go in for a much bolder and more comprehensive scheme than that put forward on the last occasion, with a view to not only providing the necessary extension of plant, but also effecting greater economy in working. The outcome was the scheme now submitted, and which had been approved by Mr. J. F. C. Snell, the Corporation's consulting engineer. He referred to a letter of the County of Durham Electric Power Supply Co. offering to limit the supply of three-phase power to that which Smith's Dock Co. might require, any further supply of three-phase current being given only with the consent of the Corporation, and intimated that they were prepared to modify their proposals to such an extent as would enable the Corporation to make a saving of £1,500 per annum.

In reply to the inspector (Mr. H. R. Hooper), Mr. SHAW (for Smith's Dock Co.) agreed that the position now was amended to the extent that the proposals which the company were now prepared to submit would effect a saving to the Corporation of £1,500 on the proposals which the Corporation submitted at the last inquiry.

Mr. J. F. C. SNELL outlined the new scheme, which he considered an admirable engineering proposition, which would prove advantageous to the Corporation and result in considerable economy. He felt bound, after a most exhaustive consideration of the situation, to advise the Corporation not to entertain the company's proposals. The reserve fund, out of which it was proposed to take £2,500, now stood at about £10,000. The new scheme would necessitate the removal of two 100 kw. reciprocating sets, upon which the capital still undischarged was £2,500. That, however, would obviate the necessity of extending the buildings.

In reply to Mr. Shaw, Mr. SNELL admitted that, in view of the new scheme, it was a good thing for the Corporation that the last application was not approved. He did not suggest that it was unreasonable for Smith's Dock Co. to want three-phase current for their docks, but they would not gain anything by having it.

Mr. SHAW said that the Dock Co. had the advice of their consulting engineer to the contrary, and they had had the current in use at their other docks at Tynemouth and Middlesbrough for years.

It was intimated by Mr. SHAW that the County of Durham Co. were prepared to meet the Corporation's criticism of their proposals on the points to which the Corporation attached most importance, one of which was in regard to dual control, and to make a new offer which would be an amendment of the third alternative proposal originally submitted.

Mr. J. H. CAWTHRA also gave evidence.

Mr. SHAW, for the opponents, said the Dock Co. were large consumers, and were anxious to have a supply of three-phase current, which they thought was the best for them. The Supply Co. was willing to give that supply.

Mr. R. P. SLOAN outlined the new proposals of the County of Durham Co., which the Corporation had declined. In their latest offer the company were willing to modify the 21 years' agreement provided for in the original proposals to any extent the Corporation desired. He had calculated that in 1915, under the company's scheme, there would be a saving to the Corporation of £272 per annum. His company wished to have power to supply three-phase current to Smith's Dock, but to no other consumer except by the Corporation's consent and to be permitted to instal such converting plant as might be necessary from time to time in the Corporation's power station, the Corporation to supply the accomodation free of charge. The company also desired power to hire out motors to consumers who wished to have them, that being a branch of the undertaking which the Corporation had not touched hitherto. The company further proposed to instal rotary plant and lay cables sufficient to produce power to the extent of at least 3,000 kw., which was twice the amount of power that would be obtained under the Corporation's scheme. The whole of the plant and cables so installed would become the immediate property of the Corporation. The total value of those works would be approximately £15,500, towards which the Corporation was asked to pay £10,080, the amount which they proposed to spend on their own scheme. The reason the company was prepared to do that was that they knew quite well that the Corporation would not spend such an amount of money unless they intended to use the plant, and to use the plant meant to take supply from the company.

Mr. SNELL, recalled, cirticised the company's proposals. There would, he said, be considerable difficulty in converting three-phase into single-phase energy, and there would not be the same reliability of supply which there would be under the Corporation's scheme. He thought the Corporation would be extremely foolish for the saving of £272 per annum to hand over the whole control of their power station to a local company, and not to retain the whole thing in their own hands. It was a question of terms, of course, and if sufficiently generous terms were offered by the company he might not be inclined to object to the Corporation accepting

Digitized by Google

them, but on the terms offered it was not worth the Corporation's while, and he could not advise them to place themselves in the hands of the company.

After counsel had addressed the inspector the inquiry closed.

Southampton.—The borough electrical engineer (Mr. H. F. Street) has reported that the department frequently receive applications from ratepayers for supply of electricity through slot meters.

The hire purchase scheme in force does not meet the wishes of these applicants, and they insist on either having a scheme on similar lines to that inaugurated by the gas company or nothing at all, and the department has in this way lost a number of profitable customers. He recommends the adoption of both the slot meter system and the rental system, giving customers the option of either. The Electricity Committee have adopted Mr. Street's proposals.

Truro.—The Council have informed Messrs. J. B. Saunders & Co. they will be prepared to entertain the question of public electric that lighting for a number of years, provided the firm make suitable arrangements for the erection of electricity works.

Wimbledon.—A Committee has been appointed to confer with representatives of the Wimbledon Traders' Association, who demand a reduction in the price of current supplied for outside arc lighting.

Winchester.—The County Council have decided to wire the great hall of Winchester Castle at a cost of £100.

Wireless Telegraph Notes.—Another grand piece of work has been accomplished by the saving grace of wireless telegraphy. A report from New York states that the Ward line steamer "Merida," on the night of Thursday last week, off Cape Charles, Virginia, was in collision with a fruit ship, and sunk five hours after the collision, all her passengers and crew being reported saved. The "Merida" was a vessel of 4,000 tons and had 210 passengers on board. In calm but thick weather the fruit boat (the "Admiral Farragut") of 1,300 tons, loomed up in the darkness, and struck the other vessel heavily amidships. Great panic prevailed on board the "Merida," which, however, being equipped with wireless apparatus, sent out calls for assistance, and intercepted the U.S. battleship "Iowa," which was successful in saving more than 300 of her passengers and crew. Another vessel, the "Hamilton," also responded, and in due course the passengers and crew of the "Merida" were transferred to the merchant ship. All the passengers' baggage was lost, and there is some doubts as to the fate of the captain and four officers of the "Merida."

Workhouse Lighting.—The Essington Board of Guardians have agreed to obtain a specification from Messrs. Vesey Brown & Hall for the electric lighting of the workhouse.

York.—An inquiry was held here last week into the application of the Corporation for sanction to borrow £15,000 for extensions of the electricity undertaking.

The city accountant (Mr. J. W. Davison) having given statistics as to borrowing powers and the financial position of the undertaking,

Mr. Councillor (Mr. H. Craven) said that extensions were required to meet the demands for electric lighting and power and for the supply of current to the tramways. The department had now well turned the corner and was doing well. Several large consumers were negotiating with them for power supply from the Corporation instead of generating their own energy as at present, and arrangements had been made with some of these. The last extension of plant was made in 1904–5, in which year the units sold totalled 904,000. Last year they sold over 1,500,000 units, and the engineer estimated that this year the number would reach 2,500,000, and next year would be approximately 4,000,000 units.

Mr. J. W. Hawe, city electrical engineer, supplied technical details.

The Town Clerk, in answer to the inspector (Mr. H. R. Hooper), said that the reserve fund was £1,128. 14s. 5d., and of that the Corporation had just taken £800 in relief of rates. The undertaking had had £8,000 from the rates.

The Inspector: It is clear it would be much better to have put it to reserve, for it is badly needed. The ½d. in the £ (represented by the £800) will not do anybody any good. It certainly did not help the poor man, because it did not make any difference to him. He paid so much for his rates (including rates) and, if there was any deduction, he did not get any benefit. Cheap power and light was the best thing the city could have, and as an engineer with some knowledge of their station, he should have thought that the £800 would have been better left to the credit of the undertaking than placed to reduction of rates.

On the suggestion of the inspector the application was reduced by £137, the amount unexpended on the switchboard.

The London Electrical Engineers.—The third annual Athletic Sports of this unit of the Territorial Force were held at the London Caledonian Athletic Grounds, Herne Hill, on Wednesday last. The officials included: *Referee*, Major A. E. Le Rossignol; *Judges*: Major H. S. Phillips, Capt. W. H. Merrett, Capt. K. Edgcumbe and 2nd Lieut. H. C. C. Tufnell, and *Timekeeper*: Capt. P. H. Cornish, R.E. The various events with their winners were as follows:—*100 Yds. Race*, Sap. G. M. Drake; *Quarter Mile Cycling Race*, Sap. A. E. Argent; *Long Jump*, Sap. E. P. Gilman; *880 Yds. Race*, Sap. G. M. Drake; *120 Yds. Hurdles Race*, Sap. G. C. R. Stewart; *One Mile Cycle Race*, Sap. A. E. Argent; *440 Yards Running Race*, Sap. G. M. Drake; *High Jump*, Sap. G. C. R. Stewart; *Five Miles Cycling Race*, Sap. W. Clayton; *One Mile Race*, 2nd Cpl. L. L. Barnes; *Inter-Company Tug-of-War*, "B" Company; *110 Yards Swimming Race*, Sap. A. J. Monk; *440 Yards Swimming Race*, Sap. A. J. Monk. The Le Rossignol Inter-Company Challenge for the company obtaining the greatest number of points was won by "C" Company. The times were taken on a Smith's split second chronograph.

Electro-Harmonic Society.—The annual general meeting (to receive the accounts for the 25th season, to elect officers for the 26th season, and to transact the ordinary business) will be held on Thursday, 25th inst., at 6:30 p.m., at the Institution of Electrical Engineers, Victoria Embankment, London, W.C. During the past season 53 new members have been elected, seven members have been lost by death, 53 have resigned, and 18 have been struck from the register. There are now 612 names on the register. The accounts show receipts from subscriptions £311. 6s. 6d., entrance fees £13. 5s., extra concert tickets £13. 0s. 6d., brought forward £59. 2s. 1d.—total £396. 14s. 1d. Expenditure was £335. 5s.; balance £60. 19s. 1d.

COLONIAL AND FOREIGN NOTES.

Aden.—The report of the Aden Chamber of Commerce stated that a supply of electricity for lighting the town and working fans is one of the greatest needs at present. It is suggested that a Government grant might be obtained for an electricity undertaking. Oil is the present illuminant.

Argentina.—The generating station of the Cia. General de Electricidad, Cordoba, was opened on April 3. There are now two companies supplying electricity in Cordoba.

Santa Fé Municipality has refused to grant an extension of time to Winby & Co., concessionnaires for electric tramways, unless they are prepared to pay a fine.

Senor E. de Elia has applied to Buenos Ayres Municipality for a concession for the construction of surface contact tramways, partly on the street level, partly in open tunnels or cuttings, and partly underground. The Public Works Department find that some sections of the route have been granted to the Anglo-Argentine Tramways Co., that others were under National jurisdiction, and that the tunnels would interfere with the main storm water conduits. The applicant has been invited to alter his scheme.

Official statistics show that electrical goods imported into Argentina in 1910 were valued at 5,741,530 pesas (gold) (£1,148,306) compared with 4,216,914 pesas (£843,383) in 1909.

It is stated that a company has asked Villa Dolores (Cardoba) Municipality for a concession for the construction of a telephone system to connect the town with all the neighbouring townships and to extend as far as Villa Mercedes.

A North American syndicate has applied for a concession for the construction of electric tramways from the capital to the suburbs of Ensenada Los Talas, Tolosa, Abasto, Villa Elisa, and ultimately to other suburbs.

Australasia.—Eaglehawk (Victoria) Council have borrowed £6,000 for the erection and equipment of electricity works and have invited tenders for the plant.

A Conference of delegates of the municipal councils of Newcastle (N.S.W.) and its suburbs, the local Chamber of Commerce and the West Wallsend Progress Committee regarding the proposed electrification of the Newcastle district tramways recently passed a resolution that application be made to the Premier to have the electrification carried out as quickly as possible. A deputation to the Premier was appointed. £50,000 has been voted for the scheme.

Ararat (Victoria) Council has for some time desired to establish municipal electricity works, but the success of the undertaking seems to depend upon the Council's obtaining contracts for supplying the public offices and institutions in the district. For years the local gas company charged 12s. 6d. per 1,000 for gas supplied to the public and 10s. for supplies to the Government institutions. When the electricity supply project was mooted gas prices were reduced to 10s. and 8s. respectively, and when the Council's prices for electrical energy were decided upon the gas company (the Mayor of Ararat states) reduced their price to Government to 6s. 8d., with the result that the railway department has entered into a five years' contract. The Mayor asks if it is right for the Government to support the gas company, who have neglected to make necessary extensions of mains and have only made reductions of prices when compelled to do so by the enterprise of the Council. The prices at which the Council propose to supply electricity are 6d. and 3d. per unit for lighting and power respectively.

H.M. Trade Commissioner for New Zealand states that the expenditure of Wellington Harbour Board up to Sept. 30, 1911, will include electric cranes (£2,400) and electric lighting and hydraulic plant (£1,250) for J shed, and other electric lighting plant £10,000.

Customs Duties.—In conformity with a recent decree of the Finnish Senate electrical machinery imported into Finland will in future be subject to a duty of 47·10 Finnish marks per 100 kilogs. (19s. 3d. per cwt.) if not exceeding 2,000 kilogs. and if made mostly of iron; and 14·70 marks per 100 kilogs. (6s. per cwt.) if over 2,000 kilogs. All such machinery down to 100 kilogs. was formerly dutiable at 14·70 marks per 100 kilogs.

A recent customs notice issued by the Australian Commonwealth Government states that reinforced concrete poles for electric

Digitized by Google

lighting and other purposes are subject (as wooden poles) to import duty of 30 per cent. ad. val. (British goods 25 per cent.)

Under decisions of the French Customs administration, sliding rails of iron or steel for electric tramway conduits are classified under No. 213 of the Import Duties Tariff (as rails of iron or steel) if rough or simply pierced for bolts, and under No. 525 (as fixed railway material) if thinned and planed or otherwise worked

Electric Traction in Chili.—The Minister of Public Works proposes to submit to the Chambers a bill for the electrification of over 600 miles of railways. It is estimated that the necessary power will be obtained from the numerous watercourses in the county.

South Africa.—A proposal for electric lighting at Koffyfontein has been put forward by the Koffyfontein Mines (Ltd.). This will necessitate the raising of £1,000 by the municipal council, and, if carried into effect, may necessitate for the first time the levying of a rate.

The De Beers Co. have offered to reduce the price of Kimberley Council's bulk supply of electrical energy from 5¼d. to 2¾d. per unit, if the Council agree to reduce the price to consumers to 6d. The Railway Department recently asked for the Council's terms for a supply.

Bulawayo have agreed to pay the Waterworks Co. £1,500 per annum for public electric lighting, including extensions, provided the company came to a satisfactory arrangement with the Electric Lighting Committee with regard to the tariff for private consumers.

Mr. John Roberts, borough electrical engineer, has presented to Durban Corporation a report on the investigations made by him in England, Germany, Holland and Belgium. The report states that in England the conditions as regards electrical undertakings are generally similar to those in Durban. Considering the population, the extent to which electricity is employed at Durban compares favourably with what is done by most English municipalities, and in many instances Durban is ahead. This is to be accounted for by the absence of gas competition. In England the gas companies have vastly improved their methods of applying gas for illuminating purposes, notably by the use of the inverted mantle, and efforts appear to have been made to copy all the features which have made electricity popular.

Uruguay.—The "Review of the River Plate" states that a project, in which foreign capital is interested, has been put forward for an electric railway from Montevideo to Punta del Este, a seaside resort on the Atlantic coast.

The Minister of Public Works is considering a proposal to municipalise and electrify the railway and tramway del Norte.

A British syndicate has presented to the Government a proposal to hold an international exhibition at Montevideo in 1912, with sections for automobiles, aviation, &c.

The states that the Government have not accepted the offer of one of the existing telephone companies to alter its overhead lines, and the President states that the Minister of Industries will study the matter and confer with him (the President), and then insist on the original scheme or introduce amendments convenient for general interests. Our contemporary says this means that the companies are to be frozen out.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Bournemouth.—The annual report of the tramways department states that the total income for the year ended March 31 was £89,767, and after paying expenses, the gross profit was £32,018. After allowing for interest and redemption of stock and loans, rent of leased lines, &c., there is a net deficit of £153.

Bradford.—The net profit on the past year's working of the tramways was £39.374, compared with £32,364 in 1909-10.

The traffic receipts were £256,063 (11·25d. per car-mile), against £245,682 (10·846d.), an increase of £10.380. Traffic expenses (£63,822) show an increase of £177; but on the basis of car-mileage they are slightly less, being 2·804d., compared with 2·825d. Repairs and maintenance came to £32.287, or £139 less; but the cost of electric power showed an increase of £752, being £47.717 (2·097d. per car-mile), compared with 2·073d.). Wages of traffic employés and accident compensations and insurance also showed increases. A sum of £22,000 has been devoted to relief of rates, an increase of £10,000. The income of the parcels department for the year was £8,257, and the expenses £6,599, leaving a surplus of £1,658. Interest on loans showed a decrease of £851, and sinking fund charges an increase of £240. The balance brought forward was £44,006, and adding to the surplus of £39,374 the total is £83,380. During the year the sum of £13,135 was expended upon renewal of track and £20,000 was transferred to relief of rates, leaving a credit balance of £50,244.

Burton-on-Trent.—The accounts of the electricity department for the year ending March show total income £13,089, of which £12,620 was for energy sold, being 1·81d. per unit (compared with 1·875d. in previous year).

Works costs were £4,402=0·631d. (0·712d.) per unit; rents, rates, and taxes £643, or 0·093d. (0·107d.) per unit; management, printing, insurance, &c., £593, or 0·085d. (0·099d.) per unit; total £5,639, or 0·809d. (0·918d.) per unit. Interest and contribution for redemption of loan required £5,082, or 0·730d. (0·808d.) per unit, and the net profit was £2,364, or 0·339d. (against £1,474, or 0·230d. per unit in previous year). Units sold were 1,672,460 (against 1,529,600) including private lighting 323,070 (300,774), public lighting 1,350 (1,190), motors, 690,210 (544,484), heating, &c., 14,585 (16,120), Corporation tramways, 591,847 (617,199), and Ashby Light Railway, 51,398 (49,833). There are 675 (against 605) lighting, and 84 (76) power consumers, the (equivalent) 8 c.p. lamps connected are 37,045 (34,829), and motors connected are 173 (150) with an aggregate capacity of 1,087 (933) H.P. The maximum loads were 524 kw. (500 kw.) for lighting and power and 375 kw. (375 kw.) for traction, the combined load factor was 21·2 (19·95) per cent. and the plant capacity is 1,710 kw. (as in previous year). Average prices obtained were: For private lighting 4·65d. (4·86d.), public lighting 3d. (3d.), power and heating 0·909d. (0·974d.) and traction 1·37d. (1·37d.). £1,138 is being placed to renewals fund and £1,000 contributed to relief of rates, this being the first contribution made by the Department for the latter purpose. Although units sold show 9·35 per cent. increase, cost of fuel is down £91, due to strict supervision of the boiler house and to the use of lower grade fuel to a greater extent than heretofore, and a further £21, due to depreciating the stock of coal by 1s. per ton. All repairs to outbuildings, mains, mchinery and meters have been paid out of revenue.

The accounts of the tramways department for the year to March last show capital expenditure on the Corporation lines £94,803 and on leased lines £11,210, total £106,012. Of this sum £57,611 has been repaid, and the outstanding debt is £57,611. Total revenue was £15,368 8·52d. per car-mile (against 8·47d. last year), including £936 (£932) from Midland Railway Co. for running powers. Operating expenses were 6·41d. (6·47d.) per car-mile exclusive of Midland Railway Co.'s running, the total working expenses, including power, management, &c., being £12,255 and the gross profit £3,113. After meeting capital charges and placing £1,000 to renewals fund there is a deficiency of £682 (against £2,756); 3,131,172 (3,082,804) passengers were carried and 432,911 (428,219) car-miles run.

The accounts of the electricity supply and tramway departments were approved by the Corporation last week.

Bury.—The accounts of the Corporation tramways department for the year ended March show capital expenditure £282,894 (increase £1,748.) Total of sinking fund is £31,200, of which £12,600 has been applied in reduction of debt, and the reserve or renewals fund amounts to £15,361.

The total revenue during the year was £60,696; working expenses were £34,250 and gross profit was £26,447, from which have to be deducted amount due to Salford Corporation, being the receipts less working expenses of the Salford sections (£657), amount carried to joint tramways account, arrived at similarly in respect of the Radcliffe sections £4,574, Heywood sections £3,610, and proportion of special cars, parcels, &c., £23, leaving £4,469 net profit on the Bury section, of which £1,669 has been carried to borough rates and £2,800 to reserve. Car-miles run were 1,573,686 and the passengers carried were 13,236,628. Total revenue per car-mile was 9·26d. and working expenses per car-mile, including power, were 5·552d. The average fare per mile was 0·85d.

Ipswich.—The accounts of the electric supply department for the past year show a surplus, after meeting working expenses and interest on and repayment of loans, of £1,744, compared with £1,080 in 1909-10.

After paying off certain items, including expenditure on street lamps, arc lamps on hire, the last instalment of preliminary expenses, purchase of meters and wages of permanent employés engaged on capital works, there remains £554 which has been transferred to reserve, the latter fund now standing at £1,456. The department seems to have made excellent progress during the year. Excluding the installation department, the total revenue was £15,619, an increase of 10·3 per cent., while working expenses and capital charges increased by only 6·5 per cent. The revenue of the installation department was £3,875, an increase of 27·34 per cent., while the profit (after making due allowance for depreciation of stock), was £186. In addition, wiring on the rental system was installed to the value of £527. The total connections (in kilowatts) are now 2,796, excluding traction supply. The maximum load (including traction) was 1,147kw. Gross capital outlay is £93,481.

The accounts of the tramways department show a deficit on the year of £2,229, against £1,732. This, however, does not represent the whole charge on the rates because the Council have decided, upon the recommendation of the engineer and manager (Mr. F. Ayton), to provide a renewals fund for relaying the entire track within 15 years from the opening of the line. The rates have contributed to this fund during the past year £1,400, but in future the annual instalment is to be £3,421. The passengers carried totalled 5,240,242, the car-miles run being 676,255. The total revenue was £21,738 or 7·714d. per car-mile, compared with £20,883, or 7·775d. per car-mile in 1909-10. Working expenses were £17,952, or 6·371d. per car-mile. The increased deficit is due to cost of repairs to cars and track. The Committee have decided to make the charge for power for the tramways 1½d. during the current year and to consider at the end of the year whether to give a further reduction in the form of a rebate.

Leeds.—The accounts of the electric lighting department for the year to March 31 show capital expenditure £1,005,174, the amount outstanding being £735,407, and the increase during the year £19,118.

Revenue was £104,468 (against £99,068 in previous year) and gross profit £71,326 (£69,288), income tax required £924, interest £28,633 and redemption fund £32,701. The surplus profit (which has been carried

Digitized by Google

to relief of rates) is £9,993 (against £8,931). The maximum load was 7,800 kw., or 9,140 k.v.a. (increase 240 k.v.a.), and the capacity of the plant is 15,740 kw. Consumers of energy for lighting are 6,655 (against [illegible] in previous year) and for power and heating 1,351 (against 1,127), the equivalent 35-watt lamp connections being 315,508 (311,812) for lighting and 367,236 (320,917) for power and heating. There are 2,452 [illegible] motors in use, their aggregate being 14,689 H.P. (12,836). Units sold were 14,372,765 (12,421,164), of which 4,460,328 (4,575,957) were supplied for private lighting, 926,351 (937,193) for street lighting and [illegible],008,014) for power and heat. Units sold (for all purposes) per (equivalent) 35-watt lamp were 21·65 (20·66) and revenue was 3/0·71 [illegible] per (equivalent) 35-watt lamp. Total working expenses per unit sold were 0·52d. (0·59d.) and total expenses, including wages on extensions not chargeable to loans account, extraordinary renewals, interest, and redemption fund, 1·58d. (1·74d.). The average price [illegible] was 1·74d. (1·91d.).

A statement accompanying the accounts points out that the metal filament lamp has continued to affect the profit-earning capacity of the undertaking, but there are strong indications that the period of diminishing revenue is drawing to a close, as the decrease in lighting sales is (for the first time) more than counterbalanced in money by the increased sales for power and heating, and the total revenue exceeds that of the previous year. The working expenses per unit sold are the lowest on record. There is an increase of £1,494 in the amount provided for payment of debt and the total expenditure increased by £4,338.

Loughborough.—At the meeting of the Council last week Ald. Bowers reported that the gross profit on the electricity department for the year ended March 31 was £1,874, an increase of £1,020 over 1909-10.

Ald. Bowers said they could not credit the whole of the improvement to the improved working of the undertaking, inasmuch as there was a credit for paying off a battery which expired last year. There had been a large increase in the output, particularly for power. The increase in the output for power amounted to 50 per cent., and that for lighting from 12 to 15 per cent. The cost of producing current had gone down from nearly 2½d. in 1908 to 2d. in 1909 and 1¼d. in 1910. This year it was 0·9d. exx. The standing charges were £2,203, leaving a deficit of £330, against which there was a grant from the general district rate of £1,500 towards redemption on the year's work and the deficit which had accumulated. The balance of that £1,500 went to the previous deficit, less £330 deficit of the present year.

Morecambe (Lancs.)—On the past year's working of the tramways department the profit was £1,272. 16s. 1d., out of which £1,000 has been devoted to relief of rates.

Preston.—The gross profit on the tramways for last year was £5,451, and the net profit (£4,369) has been added to reserve.

The total income for the year was £37,490, against £37,840; the passengers carried were 8,412,567, against 8,484,589. Parcel traffic increased by £283.

Rotherham.—The net profit on the tenth year's working of the electricity department was £3,740, against £2,922 in 1909-10. The gross receipts on the tramways department were £33,314, against £31,959.

Mr. Winter and the tramways manager (Mr. E. Cross) have been authorised to visit places on the Continent for inspecting systems of overhead trolley traction.

West Bromwich.—The sale of current by the municipal electricity department for the past year shows an increase of 8.23 per cent. over the figures for 1909-10.

Private lighting revenue was £364, a decrease of £19; public lighting [illegible] the same as the previous year; tramway traction power £4,756 [illegible] £50, and motive power £5,103, increase £1,660. The net [illegible] for the year is £1,079.

West Hartlepool.—At the last meeting of the Council it was reported that the past year's working of the electricity department, after providing for all charges (including sinking fund and interest), showed a surplus of £1,505. 12s. 9d., which it was recommended should be carried to reserve.

The average price of coal was 9s. 7½d. per ton, compared with 10s. [illegible] of debt repaid during the year was £3,454, and interest on loans [illegible] £2,717. The gross profit (£7,476) was nearly 7¾ per cent. on the [illegible] capital employed. Out of a total capital of £92,000, £32,000 has been repaid.

Yarmouth.—The accounts of the tramways and electricity supply undertakings for the year ended March 31 were presented to the Council on Tuesday.

The total tramway revenue was £23,830, increase £507; and after paying all expenses the net profit was £8,126, compared with £6,588 for the year. After paying interest, sinking fund and income tax, the balance of £413. 6s. 6d. was added to appropriation account, compared with £268. 4s. 1d. for the year, and £1,250 to general renewal fund. Nearly 4,500,000 passengers were carried, an increase of 75,000.

The statement of the Committee (Ald. Campling) said that the cost of power had decreased by £645, owing to a reduction in the charge and the fixing of meters which had been introduced. He anticipated effecting a further saving of £200 or £300 in the cost of current by the use of meters.

The accounts of the electricity undertaking showed a gross trading profit, after charging £241. 10s. 7d. for converting public lighting arc lamps to incandescents, of £8,267. Of this, £431 was written off cost of meters, transformers and other works for which there is no sinking fund, £7,466 applied to interest, sinking fund, &c., and £370 added to appropriation account, making it £1,249. 19s. 8d. A sum of £982. 10s. has been added to reserve, increasing this to £4,000.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

HAMMERSMITH (London) Borough Council invite tenders for supply and erection of high-pressure steam and feed-water pipes, exhaust steam feed water heater and circulating water pipes, steam valves and feed water heaters, and feed pump. Specification and form of tender from the borough electrical engineer (Mr. G. Gilbert Bell), 85, Fulham Palace-road, W. Tenders to the town clerk (Mr. H. Thompson), Town Hall, Hammersmith, London, W., by 4 p.m., May 31. See also an advertisement.

DEWSBURY Corporation invite tenders (by mid-day May 30) for supply and laying of feeder cables and erection of feeder switchboards. Specifications and forms of tender from the borough electrical engineer (Mr. R. H. Campion), 93, Bradford-road, Dewsbury. See also an advertisement.

STEPNEY (London) Borough Council invite tenders for 12 months' supply of ampere-hour meters, demand indicators and time switches and arc-lamp carbons. Specifications, general conditions and forms of tender from the borough electrical engineer and manager (Mr. W. C. P. Tapper). Tenders must be delivered at 27, Osborn-street, London, E., by noon June 8. See also an advertisement.

Tenders are invited (up to June 27) for supply of 1,400 protectors for use on main distributing frame at magneto exchanges to the Postmaster-General's Department, VICTORIA. Tender forms and specifications at the Commonwealth Office, 72, Victoria-street, London, S.W. See also an advertisement.

SOUTH SHIELDS Corporation want tenders by May 24 for supply and erection of 1,500 kw. high-pressure steam turbine (with surface condenser and pumps) coupled to 1,000 kw. d.c. generator (with switch panel, &c.) and 1,100 kw. a.c. generator (with switch panel, &c.). Specification, &c., from the Borough Electrical Engineer.

CARDIFF Corporation want tenders by 10 a.m. May 20 for rewiring and fitting (for electric lighting) the Corporation Baths, Guildhall-crescent, Cardiff. Particulars from the City Electrical Engineer.

MANCHESTER Electricity Committee require tenders by 10 a.m. May 30 for steam pipes, valves, &c., for Dickinson-street station and for supply of two 8-ton overhead hand cranes for sub-stations. Particulars from the City Electrical Engineer.

LIVERPOOL Overhead Railway Co. want tenders by 10 a.m. June 6 for 12 months' supply of electrical fittings, insulating tapes, ironmongery, &c. Forms of tender, &c., at 31, James-street, Liverpool.

HACKNEY (London) Council require tenders by 7 p.m. May 25 for supply of 100,000 pairs of yellow flame carbons during the year to March 31, 1912. Specification, &c., from Town Clerk.

HANDSWORTH (Staffs.) Council require tenders by noon May 24 for cables for lighting and tramway purposes. Specification, &c., from Messrs. Kennedy & Jenkin, 17, Victoria-street, London, S.W.

WORTHING Corporation require tenders by noon June 12 for supply and erection of two Diesel oil engines and c.c. generators. Specification, &c., from the Borough Electrical Engineer.

ST. PANCRAS (London) Council require tenders by noon May 31 for 12 months' supply of Welsh and other steam coal to their electric stations.

CLACTON Council require tenders by noon, May 22, for 12 months' supply of electric service fittings, joint box compound, ironmongery, oils, &c.

Tenders are invited up to July 25 for the supply of 12 sections of a branching multiple magneto lamp signalling switchboard, &c., or one automatic or semi-automatic switchboard, &c.; up to June 14 for supply of a branching multiple magneto lamp signalling switchboard at Ballarat, and a c.b. multiple switchboard to the Postmaster-General's Department, SOUTH AUSTRALIA; and up to June 7 for the supply of 2 nauts single-core submarine cable to the Postmaster-General's Department, NEW SOUTH WALES. Tender forms, &c., from 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, MELBOURNE (Victoria), will receive tenders until 3 p.m. June 13, for the supply of electric lighting

Digitized by Google

material. 12 accumulators and 400 cable distributing boxes and chemicals and glassware for batteries.

Tenders will be received at the Town Clerk's office, AUCKLAND, N.Z., until 4 p.m. of Thursday, June 15, for supply and erection of machinery for the new power station, including water-tube boilers, feed pumps, economisers, conveyor and steam pipes, and induced draught plant; d.c. steam generators, condensers, auxiliary machinery, &c. Specifications, &c., at the offices of the High Commissioner, 13, Victoria-street, London, S.W.

The Town Clerk, WANGANUI, N.Z., will receive tenders until July 12 for supply of generating plant, gas producing plant and battery and booster for the Corporation tramways. Specification can be seen at 73, Basinghall-street, London, E.C. Local representation is necessary.

NAPLES Municipal Authorities require tenders by July 9 for supply and installation of the following plant in connection with the supply of electric power to Naples from the river Volturno:

1. Tubing and accessories for harnessing the water at rate of 7,000 litres a second and for the fall of 190 meters; upset price 702,900 lire (£28,116.)

2. Machinery and apparatus for hydro-electric power station, transmission line (about 57 miles), and transforming station; upset price 1,000,000 lire (£40,000.)

Tenders to Presidente del Consiglio Generale dell' Ente Autonomo Volturno, Naples.

Manufacturers who are prepared to supply 600 km. (372 miles) copper wire 8 mm. dia. are invited to communicate with the Direzione dell' Ente Autonomo Volturno, Naples, who after two months from April 10 will send invitations to tender to firms whom they consider suitable.

Conditions of tender, &c. (in Italian) may be seen at 73, Basinghall-street, London, E.C.

Tenders will be received at the Italian Royal Arsenals, SPEZIA and VENICE, until 11 a.m. June 2, for supply of electric cables and wires (estimated total amount £1,420). Specification (in Italian) may be seen at 73, Basinghall-street, London, E.C.

COPENHAGEN (Denmark) Lighting Corporation want tenders by noon, May 23, for supply of about 3,000 electric meters. Specification (in Danish) at 73, Basinghall-street, London, E.C.

Tenders will be received at the Bourse, BRUSSELS, on May 24 for supply of telegraph cables.

Tenders will be received at the Post and Telegraph offices, PARIS, on May 30, for the supply of 100 tons of 2 mm. and 50 tons of 3 mm. bi-metallic wire.

TENDERS RECEIVED AND ACCEPTED.

London County Council have accepted the following tenders:—

Ibbotson Bros. & Co., bolts and nuts for renewable guard rails, &c., £1,546. 11s. 3d. (Three tenders, varying from £1,546. 11s. 3d. to £1,742. 3s. 9d.); Rees Roturbo Pump Co., electrically-driven pump for driving water from cable manholes, at £110. 10s. Gwynnes (Ltd.) also tendered at £170. 17s. 6d.

The following tenders were received by London County Council for the supply of renewable guard rails:—

Walter Scott (Ltd.) (*accepted*) sandberg (high silicon), manufactured at Leeds), **£9,700** and (high carbon composition, manufactured at Leeds) £8,750.

P. & W. MacLellan, sandberg (high silicon) process (manufactured by Phœnix Steel Works, Germany), £8,168. 15s.

Six firms who were invited to quote for the work were unable to do so, while two tenders were received for the supply of the guard flange section only. The chief engineer's estimate comparable with the tenders is £8,550. The lowest complete tender received was that of P. & W. MacLellan, which provided for the rails, &c., to be manufactured by the Phœnix Steel Works (Germany) by the sandberg process. The Highways Committee were advised that, in addition, the royalty and supervision charges, which were not included in the tender, together with the cost of sending an inspector to Germany, would increase the cost of the work by about £600. The Committee reported having given special attention to the question of the material to be employed in the manufacture of the rails. They understood that a large number of railway and tramway undertakings had for some years past used rails made under the high silicon process, and that very satisfactory results as to the life of the material had been obtained, with consequent saving in expenditure on maintenance. An experiment which was made on a certain section of the Council's tramways, which had been open for public traffic since November, 1907, confirmed the result of the experience on other systems, and tended to show that the life of rails made of that material should be considerably greater than that of rails made of ordinary steel. After careful consideration they had come to the conclusion that the Council's interests would be best served if it accepted the tender of Walter Scott (Ltd.) for the manufacture, supply, &c., of the rails in England by the Sandberg process. The amount of this tender did not include payment for royalties, which would amount to about £300. In addition to the difficulties of inspection, &c., considerable inconvenience is experienced in obtaining work of this nature from abroad, as it is necessary to obtain large shpiments at a time instead of small quantities, as will be required in this particular case.

Bermondsey (London) Council have received the following tenders:—

Boilers.

Howden Boiler Co. (*recommended for acceptance*), **£5,830** and £5,936; British Niclausse Boiler Co., £6,510; Hawksley, Wild & Co. (incomplete), £7,205; Clarke, Chapman & Co., £8,185; Babcock & Wilcox, £7,619, £6,937 and £7,230.

Steam Dynamo.

Siemens Bros. Dynamo Works (Howden engine) (*recommended for acceptance*), **£6,052,** (Belliss engine) £6,447, (Musgrave engine) £6,678; John Musgrave & Sons (Siemens dynamo), £9,749; British Westinghouse Co., (Howden engine) £6,391, (Browett, Lindley engine), £6,761, (Belliss engine) £6,781; Browett, Lindley & Co., (Bruce, Peebles dynamo) £5,985, (British Electric Plant dynamo) £6,067, (E.C.C. dynamo) £6,366; British Thomson-Houston Co., (Howden engine), £6,634, (Browett, Lindley engine) £7,002, (Belliss engine) £7,106; Crompton & Co. (Belliss engine), £6,761. 10s., (Howden engine) £6,561. 10s., (Browett engine) £6,761. 10s.; British Electric Plant, (Howden engine) £5,850. 10s., (Browett engine) £6,210, (Belliss engine) £7,502. 10s.; Jas. Howden & Co. (Siemens dynamo), £6,102, (G.E. Co. dynamo) £6,149, (Crompton dynamo) £6,130, (Bruce Peebles dynamo) £5,960, (E.C.C. dynamo) £6,286; Bruce Peebles & Co. (Howden engine), £5,840, (Browett engine) £6,295, (Belliss engine) £6,530; Dick, Kerr & Co. (Browett engine), £6,515, (Howden engine) £6,194; Electric Construction Co., (Belliss engine) £6,624, (Browett engine) £6,581, (Howden engine) £6,224; General Electric Co. (Belliss engine) £6,413,, (Browett engine) £6,351, (Howden engine) £6,003.

Condenser.

Edward Deane & Beal (*recommended*), **£5,030** and £4,155; Ledward & Beckett, £7,140 and £6,276; Geo. Scott & Son, £3,533 and £3,217; British Electric Plant Co., £7,300.

Electrically-driven Boiler Feed Pump.

General Electric Co. (*recommended*), **£351** and £255; Hayward Tyler & Co., £650; Rees Roturbo Mfg. Co., £261; British Westinghouse Co., £245; Holden & Brooke (not to specification), £209; Nichols Bros., £425.

The Finance Committee have been considering a request by the Electricity Committee to submit an estimate for the purchase of the above plant, but as the Finance Committee are not satisfied that the question of obtaining a bulk supply from an electric supply company has been exhausted, they have deferred the question so that the Electricity Committee may give further attention to the matter.

Fulham (London) Council recently received the following tender for generating plant:—

British Thomson-Houston (*accepted*) (*a*, turbo-alternator) £3,240 (*b*, condensing plant) £1,292; Richardsons, Westgarth (*a*) £3,145, (*b* £1,060; Brush Co., (*a*) £3,300, (*b*) £1,151; C. A. Parsons & Co. (*a*) £3,67 (*b*) £970; General Electric Co., (*a*) £3,372, (*b*) £1,161; British Westinghouse Co. (complete plant), £4,715; J. Musgrave & Sons, (*a*) £3,333, (*b* £1,251; Belliss & Morcom (complete plant), £5,350; Willans & Robinson, (*a*) £3,346, (*b*) £1,140; J. Howden & Co., (*a*) £3,360, (*b*) £1,190 Dick, Kerr & Co., (*a*) £3,370, (*b*) £1,259; W. H. Allen, Son & Co., (*b* £1,389; Mirlees, Watson Co., (*b*) £1,250; Worthington Pump Co., (*b* £1,254.

The Electricity Committee, in reporting on the tenders, stated that the lowest tender for the turbo-alternator which complied with the specification and provided the necessary governing and efficiency tests to be carried out at the makers' works prior to delivery was that of the British Thomson-Houston Co., for £3,240. Messrs. Parsons were the lowest for the condensing plant, but they were not prepared to accept that portion of the contract only. The next lowest was that of Messrs. Richardson Westgarth (at £1,060), in addition to which, however, they required £ in the event of their condensing plant being ordered separately. The committee were advised that the length of the Curtis machine quoted for by the British Thomson-Houston Co. was about 18 ft. 6 in., against 25 ft. 8 in. required by the Richardsons, Westgarth machine, and considerable economy in the comparative cost of the necessary foundations and alterations to the existing buildings would be effected by accepting the Curtis turbine. In all the circumstances, having regard to the adaptability of the Curtis turbine to the available space at the works and the desirability of the whole responsibility as to the efficiency resting with one reputable firm only, the committee had decided (subject to the usual sanction) to place the contract with the British Thomson-Houston Co. for the complete plant.

Marylebone (London) Council have accepted the following tenders for annual supplies for the electricity undertaking:—

Le Carbone (Ltd.), carbons, brushes; Middleton Bros., oils; Aube Grenier & Co., underground cables; Sykes & Sugden, disconnecting boxes and c.i. pits; W. T. Henley's Telegraph Works Co., meter boards; Avon India Rubber Co., rubber tubing and manhole rings; Siemens Bros. & Co., para rubber strip and black adhesive tape; Pooley & Austin, white Silesian tape; St. Helens Cable & Rubber Co., rubber gloves; Callender's Co., Sykes & Sugden and W. Lucy & Co., house service boxes; F. Bird & Co., c.i. piping.

Marylebone Council have also accepted the tender of C. A. Parsons & Co. for a commutator (£220) and that of the Electrical Power Storage Co. for truck capable of carrying 15-20 cwt. (£260).

Bath Electric Light Committee have accepted the tender of the Diesel Engine Co. for a Diesel oil engine, direct-coupled to a 450 k.w. Dick, Kerr d.c. dynamo at £5,451; and that of Dick, Kerr & Co., for a 300 k.v.a. motor alternator at £1,140.

Digitized by Google

Chelsea (London) Council have accepted the tender of E. A. Rockalls (at £280) for illuminating the Town Hall, &c., for the Coronation.

Greenock Corporation have placed an order with the British Westinghouse Co. for a turbo-alternator and condensing plant, at £5,987, subject to the Secretary of Scotland sanctioning the expenditure.

Helsby Corporation have placed an order with Venner & Co. for Hookham tramcar meters. The firm's tenders for ordinary meters for Govan, Kirkcaldy and Salford have also been accepted.

Ilkeston Council have placed an order with Callender's Cable & Construction Co. for cables, and that of Ferranti Limited for meters.

Ilkley (Lancs.) Council have accepted the tender of Mather & Platt for a centrifugal pump for the electricity generating station.

Newport (Mon.) Council have accepted the tender of Walker & Co. for a motor chassis for the tramway tower waggon, at £520.

Hereford Council have accepted the tender of Mather & Platt for auxiliary electric pump at £109.

Isle of Thanet Joint Hospital Board have accepted the tender of Gray & Hopper for telephone and bell work at the hospital.

Winchester Council have accepted the tender of E. Green & Son for new sections of economiser pipes at £67.

Woolwich Council have accepted the quotation of C. A. Parsons & Co. for the renewal of a commutator at £95.

Stockton-on-Tees Council have accepted the tender of Richardson, Westgarth & Co. for a 400 kw. turbo-alternator at £2,293.

Selby Council have accepted the tender of Mr. Sykes for public lighting by 50 c.p. electric lamps, at £37 per annum.

Sydney (N.S.W.) Council recently decided to purchase, at the estimated amounts given, 50 Mannesman steel poles from Noyes Bros., at £75; 25 50-ampere 480-volt and 200 10-ampere 240-volt d.c. meters from Ferranti Ltd., at £568. 2s. 6d.; six maximum demand indicators from W. G. Watson & Co., at £34; 150 steel poles from Stuarts & Lloyds, £990.

Commonwealth Contracts.—The following tenders have been accepted by the Australian Postmaster-General's Department:—

Queensland.—Lamson Store Service Co., pneumatic tube installation, £645; India Rubber, Gutta Percha & Telegraph Works Co., Western Electric Co., British Insulated & Helsby Cables, International Electric Co., Siemens Bros. Dynamo Works, British General Electric Co., Lawrence & Hanson, Jas. Paton & Co., and Ringdahl & Co., various telegraph apparatus, material, &c.

South Australia.—R. Johnson, Clapham & Morris, h.d. copper wire and rods; W. G. Watson & Co., 5,000 insulators (£104); British Insulated & Helsby Cables, telegraph apparatus.

BUSINESS NOTICES.

Messrs. Neville Williams & Co. inform us that the Tinol branch of their business has been converted into a limited company and in future all communications relating to Tinol should be addressed to Tinol, Limited, 80A, Southwark-street, S.E. Messrs. Neville Williams & Co. are continuing the electrical manufacturing business as before.

From the 24th inst. the offices of the Kent Electric Power Co. will be transferred to Railway-street, Chatham.

The telephone number of Messrs. Spencer Chapman & Messel is Avenue 1588 (3 lines).

Edgar Hy. and Chas. Hy. Harrison (trading as Harrison & Co., electricians, &c., 35, Broadway, Cricklewood, have dissolved partnership. Debts by Mr. E. H. Harrison.

Sale by Auction.—Messrs. Horne & Co., 35, Old Queen-street, Westminster, S.W., will sell by auction at the Royal Arsenal, Woolwich, at 11 a.m. on Tuesday, May 23, unserviceable and obsolete machinery, including iron and steel scrap, brass, copper, gunmetal, lead, antimony, zinc, &c., electric cable, lathes and tools, pumps, electrical instruments, lamps, &c. May be viewed at the Royal Arsenal, Woolwich, on Friday and Monday, prior to and on morning of sale. Catalogues at the War Office, Whitehall, the Ordnance Office, Tower, and the Ordnance Office, Royal Arsenal, Woolwich. See also an advertisement.

Plant for Sale.—Messrs. Rudders & Paynes, Chester-street, Birmingham, advertise for sale three dynamos, with resistances, switchboard instruments, &c.

Patent Development.—The proprietor of Letters Patent No. 11,154, dated 1909, relating to "Batteries and Battery Holders," desires to dispose of same or to grant licences, with a view to the adequate working thereof in this country. Inquiries to Messrs. Cruikshank and Fairweather (Ltd.), 65-66, Chancery-lane, London, W.C.

Holiday Guides.—We offer no apology for calling attention to the excellent "guides" which are being issued by the leading railway companies in connection with the holiday, health and rest resorts, which are to be found upon their respective routes. The *Great Central Railway Co.* issue a group of interesting and serviceable particulars which can be obtained at any of the company's stations, or at their Goods Receiving Offices, or direct from the Publicity Department, 216, Marylebone-road, London, W.C.

The *London & South Western Co.*, whose service reaches many of the most popular and desirable of the holiday resorts of the country, have just issued a new guide which contains a mass of readable matter, helpful to those in search of where to go and how to get there. This guide can be obtained from the company's booking offices, from their various publicity establishments, or direct from Waterloo Station.

The guide which is edited by Mr. Percy Lindley, and which relates to the *Great Eastern Railway Co.'s* arrangements for their tourist traffic, has just been issued, and can be obtained at the G.E. booking offices, or direct from Liverpool-street Station, London, E.C.

"Record of Sports."—From the Royal Insurance Co., Liverpool, we have received a copy of the eighth edition of the "Record of Sports."

Nearly every kind of sport is dealt with and the volume forms an accurate and up-to-date record of sports. Its new features include a comprehensive series of notable performances and events of aviation, while the records of many other sports have been amplified and the summaries and tabulated statements have been retained.

BANKRUPTCIES, LIQUIDATIONS, &c.

On Friday at the Official Receiver's offices, Liverpool, a meeting was held of the creditors of the British Tungsten Lamp Co. (Ltd.), Huyton Quarry, near Liverpool.

The Deputy Official Receiver (Mr. T. W. J. Britten) said that, although the winding-up order had been made as far back as March 28, the statement of affairs was not yet complete. Mr. H. Lonsdale, the receiver and manager at Liverpool, had advertised the business for sale as a going concern. The unsecured liabilities amounted to £1,549, and the assets were estimated to realise £11,159, leaving a deficiency, after the debenture holders had been reckoned with, of £13,210, or total unsecured liabilities £14,759, and no assets available to meet them. The deficiency account showed a gross profit of £1,780 from the date of the formation of the company in December, 1903, to the date of the winding-up order. No resolutions were passed, but at a subsequent meeting of contributories a resolution was passed that the Official Receiver should continue as liquidator.

John Dennis Carlmark, electrical engineer, 402, High-street, West Bromwich, has been adjudicated bankrupt. The first meeting of creditors will take place on May 26 at 191, Corporation-street, Birmingham, and the public examination on June 2 at the Law Courts, Lombard-street, West Bromwich.

A first and final dividend of 9s. 5½d. is payable at the O.R.'s, Byrom-street, Manchester, to creditors of Wm. Hy. Steed, electrical engineer, &c., 13, Stamford-street, Kingsway, Altrincham.

A dividend is to be paid to creditors of Wm. Hy. Illingworth (trading as the Yorkshire Metal Filament Lamp Co.), 30, Pellon-lane, Halifax, and claims are to be sent to Mr. W. Durrance, 12, Duke-street, Bradford, by May 31.

A first and final dividend of 4s. 1d. will be payable on May 22 at at 26, Baldwin-street, Bristol, to creditors of Valentine Geo. Burkitt, electrical engineer, 38, Park-row, Bristol.

In consequence of the intention of the Company to amalgamate its business with that of May-Oatway Fire Appliances (Ltd.), the Pearson Fire Alarm (Ltd.) is being wound up voluntarily, and a meeting of creditors will be held at the office of Messrs. Fairbairn & Wingfield, 67, Watling-street, London, E.C., on May 26.

Meeting of creditors of May-Oatway Fire Appliances (Ltd.) (in vol. liq) will be held at 92 and 94, Paul-street, Finsbury, London, E.C., on May 30.

Express Cable Inventions (Ltd.) is being wound up voluntarily and Mr. R. H. Gillespie, 29A, Charing Cross-road, London, W.C., has been appointed liquidator. Meeting of creditors will be held at 29A, Charing Cross-road, on May 30.

A meeting will be held at 695, Salisbury House, London, E.C., on June 19 to receive an account of the winding up of the Cascade (1906) Power Co. (Ltd.) (in liq.).

A deed of arrangement has been executed by Arthur Brooke (trading as Fox & Co.), electrical engineer, Bradford-road, Batley. Unsecured liabilities, £917. Estimated net assets £180.

Winding-up Petition.—A petition for the winding up of J. G. Childs & Co. (Ltd.) will be heard at the Royal Courts of Justice, London, W.C., on May 30.

16,997 SIEMENS-SCHUCKERTWERKE GES. Electric speed-regulation of machines (17 7 09).
17,344 ELECTRIC & ORDNANCE ACCESSORIES Co. & GARNER. Electric circuit closers or starters.
21,339 JOHNSON-LUNDELL ELECTRIC TRACTION Co. (Lundell.) Regenerative electric motors and means for controlling the same.
28,022 ZEISS. Telemeters having two objective reflecting systems, two objective lenses and an ocular system. (17 12 09.)

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Co. (Ltd.)

The seventy-eighth ordinary general meeting was held on Wednesday, under the presidency of Sir JOHN WOLFE BARRY, K.C.B.

The SECRETARY (Mr. A. R. Hardie) having read the notice convening the meeting and the auditors' report,

The CHAIRMAN said: Gentlemen, in connection with the accounts, the gross revenue for the half-year under review amounted in round figures to £670,100, against, for the corresponding half-year of 1909, £620,900, or an increase of £49,200. Messages and other receipts show an increase of £42,400, and it is satisfactory to note that the improvement in the receipts is spread over every branch of our traffic, and appears to be due to a general improvement in trade. Interest and dividends on investments and on cash at bankers on deposit, &c., is £6,800 more than for the corresponding half-year of 1909. With regard to the expenditure side of the accounts, it will be seen that the total ordinary expenses for the half-year amounted, in round figures, to £264,700, against, for the half-year to December, 1909, £250,500, showing an increase of £14,200. This increase is almost entirely due to increased expenditure at our stations, the total expenditure on this account being £13,600 more this half-year than for the corresponding half-year of 1909. About one-half of this increased expenditure is in respect of salaries and wages due to automatic promotions and to the slight augmentation in the number of our staff; rent, fuel and light is £1,100 more, and repairs to buildings £3,000 more than for the corresponding half-year of 1909. Other items included in this account show minor increases, while a few items show slight decreases. There are no other items to which I think it is necessary for me to call special attention; but, to summarise the accounts, I may say that the result of the half-year's working is an increased profit of about £35,000 when compared with the half-year to December, 1909, and we are, therefore, able to make a substantial contribution to our general reserve fund, while maintaining the payment of the usual dividend and bonus.

On the last occasion I had the pleasure of addressing you, I referred to some important renewals of some of our older cables, which we had in contemplation. A portion of this work has been carried out during the half-year, and the cost, amounting to about £37,000, has been charged against the general reserve fund. A further contribution has been made to the fund as a provision for investment fluctuations, £20,000 being taken from the general reserve fund for this purpose. The total provision on this account is now £250,000. The results shown for the whole financial year to Dec. 31, 1910, are undoubtedly satisfactory. Our message receipts reached the highest point in our history, and are well above the figures for 1900-1901, which previously held the record when they were temporarily inflated by the events in connection with the South African War. It is true the working expenses have also increased considerably; but, as I have explained on former occasions, this must inevitably follow, owing to the great increase in the number of words with which we have to deal. The number of words carried has increased during the last 10 years by about 50 per cent. This is accounted for by the important reductions in the rates which, I am glad to say, we have been able to introduce from time to time, and more especially in recent years. The effect of judicious reductions in rates, no doubt, tends to stimulate traffic and increase its bulk. This, together with a general improvement in trade, has had the effect of increasing the gross value of the traffic carried at the lower rates; but I may mention that whereas the number of words carried has increased so much, the percentage of gross revenue to capital has only increased by something under 3 per cent., so that the public are benefiting largely by the reductions to which I have referred. So long as we can efficiently deal with the larger volume of traffic without being obliged to increase our carrying capacity by additional cables, a sufficient margin of income over expenses can be maintained; but if traffic grows at the rate it has been doing during the last 10 years you must arrive at a point when additional cables are absolutely necessary to cope with the work. Therefore, it is very essential that additional cables should be provided as far as possible without increasing our capital account, otherwise the necessary margin of receipts over expenses would gradually disappear. It is when additional cables have to be paid for that we more than ever realise and appreciate the importance of our substantial reserve fund. Gentlemen, this is the policy to which we consider the success of this Company is mainly due, and we believe that the financial position achieved by harbouring our resources is in the best interests not only of the stockholders, but of the country and the telegraphing public as well. With this object in view, it is our aim to make the Company prosperous, for it depends upon the prosperity of the Company as to how far we can confer additional benefits on our customers, either by reducing rates or by providing new cables, thus giving them an improved service, not only in speed and accuracy, but also in reliability of communication. In this regard I may incidentally remark that our efforts are being directed towards the more general use of automatic signalling and recording apparatus, not only to attain increased speed, but to eliminate as far as possible errors in messages caused by the complicated combinations of vowels and consonants which make up the weird artificial words now used in codes by many of our customers. It is about 10 years since we laid any new cables of importance; but, for the reasons to which I have referred, the time is approaching for strengthening our system in the Mediterranean and elsewhere.

I think it may be useful and interesting if I review shortly the financial aspect of the Company to-day, and contrast it with the position 10 years ago, when we decided, in conjunction with the Eastern Extension Co. to establish an alternative line of cables between Great Britain and Australia via South Africa. This Company's share of that great undertaking comprised cables of large carrying capacity from Porthcurnow to Madeira, St. Vincent, Ascension, St. Helena and Capetown, a landline between Capetown and Durban, and a cable between Durban and Mauritius. When this liability of over two millions—on this Company's back alone—was incurred, our general reserve fund was under one million, but subsequent events proved that this important step was fully justified. Owing to the substantial increases in revenue which occurred during the years following, we were able out of our surplus revenue moneys gradually to clear off this large expenditure without any increase to our capital. The balance was cleared off in 1906, since which time we have been able gradually to build up our reserve fund, and it now stands at the substantial sum of £1,620,000, after providing a quarter of a million for market fluctuations of our reserve fund investments, besides charging an additional sum of over half a million during the last 10 years for the renewals of some of our older cables.

Now, Gentlemen, I think you will agree that this is a fine record. I think it is particularly satisfactory when we consider that not only have we been able to do so much in the past, but that we have at the present time a good round sum in reserve to meet expenditure on new cables which must be laid in the near future, as well as for the renewal of some of our older sections to which I have already referred.

You may have noticed what was stated by the Postmaster-General

Digitized by Google

House of Commons on November 21 last on the subject of deferred ... at reduced rates, when he said that "proposals were under consideration for a large reduction in the cable rates charged on the chief ... routes for cablegrams in plain language and of a non-... character; but, as the adoption of these proposals involved negotiations with foreign administrations, he was not yet in a position to make a statement with regard to them." As we are always anxious to assist in any scheme which will give the sender of social messages advantages approaching those at present enjoyed by merchants and others who ... codes, thereby greatly reducing the cost of mercantile messages, we have heartily associated ourselves with the proposal, and trust ... negotiations with foreign administrations will be satisfactorily ... I will conclude by moving the adoption of the report and ... on the declaration of the dividends set out therein.

The VICE-CHAIRMAN and MANAGING DIRECTOR (Sir John ... Pender, K.C.M.G.) seconded the motion.

Mr. JOHN NEWTON said he thought that the shareholders should ... like the Directors on a record year's working, and express their ... with the manner in which the Board were dealing with the finances ... Company. He presumed the repairs which had to be made were ... subject to income tax.

The CHAIRMAN, in reply, said he was pleased Mr. Newton ... the policy of the Company—which had been pursued now ... many years—of putting an adequate sum to the Company's reserve ... thus giving a substantial basis not only to the dividend, but also to ... capital value of the shares. The question of income tax chargeable ... had been before the Directors for a long time, and had been ... with the authorities of the Inland Revenue Department, who had ... to an arrangement which the Directors thought fair and reasonable ... the lengths of cable used on repairs and renewals.

... tion was carried unanimously.

Mr. HOLMS warmly testified to the courtesy and efficiency of the staff ... of the stations which he had visited, and concluded by moving ... complimentary vote of thanks.

Mr. NEWTON, in seconding the motion, said he was sure the Directors ... fully appreciated the work of the staff, especially when its efficiency ... observed to by those who had seen it.

... tion was carried unanimously, and the proceedings terminated.

Eastern Extension Australasia & China Telegraph Co. (Ltd.)

The seventy-fifth half-yearly ordinary general meeting was held on ... at St. John Wolfe Barry, K.C.B., presiding.

The GENERAL MANAGER AND SECRETARY (Mr. F. E. Hesse) ... the notice calling the meeting and the report of the auditors.

The CHAIRMAN said: The gross receipts of the Company for the half-year under review amounted, in round numbers, to £337,000, against ... for the corresponding period of 1909, showing an increase of ... which it is satisfactory to find is spread over the whole of the ... system (applause). The working and other expenses amounted, ... numbers, to £154,000, against £143,000 for the corresponding ... 1909, showing an increase of £11,000. When I had the pleasure ... you six months ago I referred to the cost of living in the Far ... particularly in the Straits Settlements, having risen very considerably ... the last few years, and stated that your Directors had found it ... after a careful investigation of the present circumstances, to ... increase the remuneration of the staff in that region in order ... meet the new conditions which had thus arisen. This additional ... accounts for nearly £8,000 of the increased expenditure ... and as the special allowances granted to the staff towards ... last year were made retrospective from January 1, 1910, the ... represents 12 instead of 6 months' special remuneration. ... in the present accounts is consequently nearly double what ... have been under ordinary circumstances. The balance of ... expenditure, roundly £3,000, is more than accounted for by the ... charged for maintenance of cables, &c., compared with the ... period of 1909.

... the figures for the whole year, the results are as follows:— ... amounted to £682,000, against £606,000 for 1909, or an ... £76,000. The expenditure amounted to £305,000, against ... 1909, showing an increase of £6,000. Consequently the net ... year 1910 was £70,000 more than in 1909 (applause). The ... half-year was roundly £165,000, and, after adding nearly ... brought forward from the previous half-year, there remained an ... of over £227,000 (applause). The usual quarterly interim ... 2s. 6d. per share were paid during the past year, and it is ... to distribute a like amount to-morrow, making a total divi... 5 per cent. for the year. It is also proposed to pay a bonus of 4s. ... cent., making a total distribution of 7 per cent. for 1910. ... have been made during the past year to the Main... and Depreciation Funds, and, after applying ... revenue balance to the General Reserve Fund, the sum of ... carried forward.

... that the Eastern Extension and Great Northern ... have been able to assist the Chinese Govern... to reorganise, improve and develop their ... services by advancing to them for these purposes ... interest on account of, and, on the security of, the ... by the companies to the Imperial Chinese Telegraph ... under their existing agreements. In meeting the ... agreements on such terms your Directors have had in ... strengthening of the good relations which, happily, have so long existed between the Chinese Telegraph Administration and the Eastern Extension and Great Northern Companies, but also the material benefit which the expected improvement in the Chinese telegraph service would confer on their international cable service (hear, hear). The Eastern Company are assisting this Company in making this advance, and the transaction will be shown in the next half-yearly accounts as a Reserve Fund Investment.

At the last general meeting I referred to the wireless telegraph installation then in course of erection at the Company's Keeling-Cocos station to enable telegrams to be exchanged between passing ships and that remote place. The installation has since been completed and the public service was opened on the 2nd of March last. So far the traffic has been rather disappointing, but as the facilities become better known and appreciated by shipowners and the public at large, and as the shipping traffic develops, we trust that better results may be obtained. The negotiations with the British Government for extending the wireless service to the Company's Singapore, Hongkong and other suitable stations are still proceeding, and ought soon to be satisfactorily settled. When addressing the shareholders of the Eastern Company a year ago, I mentioned that the Associated Companies had long been anxious to make some special arrangement whereby a considerable addition to the volume of British imperial news might be distributed throughout the whole of the Empire, so that our colonies and dependencies might be more in touch with the facts and ideas of the mother country (hear, hear). It was not an easy matter to bring about a practical scheme acceptable to everyone, and, after much consideration and consultation with those interested in this important matter, we were able to begin a service by arrangement with Reuter's Company. The arrangement enabled that agency to have the distribution of 150,000 words per annum of imperial news at Aden, which place is en route to all the Eastern colonies and dependencies of Great Britain. I also mentioned that the news on the way to Aden, after being made use of at Gibraltar, Malta and Egypt, was sent on to South Africa, and also supplied to the British possessions on the East and West coasts of the African continent. This news service has since been granted to India, where it is giving satisfaction, and negotiations have been in progress for some time past for extending it to Australasia and the British colonies in the Far East, which negotiations, it is hoped, will soon be brought to a satisfactory termination. I now move the adoption of the report and accounts and the declaration of the dividends.

The Marquess of TWEEDDALE, K.T., seconded the resolution.

Mr. REICH: I should like to congratulate you on the very satisfactory report and balance-sheet you have put before us, and I hope the progress made during the last few half-years will continue, and that at some future time you will be able to consider the propriety of giving us a little extra dividend. I find that you have put aside £150,000 towards meeting possible depreciation in your investments. As stocks have gone up in the meantime—a circumstance on which I also congratulate you—I should like to know if this £150,000 fully covers the possible loss which might be shown in the event of the securities having to be realised. I also take the liberty of making a suggestion. It is this: We are much indebted to the staff. I suggest that they are fully deserving of some recognition in view of the event which is to take place next month. (Cheers.)

The CHAIRMAN, in reply, said: With regard to any increase of dividend, the Directors are all unanimously of opinion that it is better for the interests of the Company to keep the dividend stable and the price of the shares stable than to have a fluctuating dividend (hear, hear); and in the case of this Company, I think you will agree with me that the time has scarcely arrived even to consider the possibility of paying an increased dividend. We are able to pay a good dividend and to put such a sum to reserve as to enable us to ensure the admirable working of our Company. It is very gratifying to hear what Mr. Reich says of the staff and of the Company's service. The organisation is one of which we may all be proud, in fact, the whole nation may be proud of the cable service which is administered from these offices, and no one exceeds me in my appreciation of the zealous, intelligent and careful administration of our staff. The position with regard to our investments is this: That the valuation we have put on them in providing for fluctuations in values is approximately right at the present moment. Stocks have gone up in some cases, but our reserve funds in former years were invested in what was then considered the very best gilt-edged securities, when money was very cheap, but there is a large depreciation in those investments. Practically speaking, I think the shareholders may be assured that the sum we have put down is very nearly what the market price of the day would point out as the value of the securities, but, of course, every shareholder must know that, whatever the market price of the day, you could only realise our securities very gradually; otherwise, prices would run away, and we should have a much larger depreciation. To all intents and purposes, we have got in our allowance for investment fluctuations a fair and proper amount, on the assumption that the securities have to be realised from time to time, as they must be for the undertaking of extensive repairs or new works which have to be undertaken by the Company. With regard to the question of a bonus to the staff in connection with the Coronation, all I should like to say just now is that the matter will have the consideration of the Board. It does not merely affect this Company, but all our Associated Companies, and therefore the matter, I think, will have to be considered by a joint meeting of the various Boards.

The motion was then carried unanimously.

The retiring directors, Mr. F. A. Bevan and the Hon. A. G. Brodrick, were then re-elected as directors, and the retiring auditors were re-appointed, after which a cordial vote of thanks to the chairman, directors and staff terminated the proceedings.

West African Telegraph Co. (Ltd.)

The twenty-sixth ordinary general meeting was held on Wednesday, under the presidency of the MARQUESS OF TWEEDDALE, K.T.

The SECRETARY (Mr. John Cambrook) read the notice convening the meeting and the auditors' report.

The CHAIRMAN then said: The gross revenue for the year under review amounted to £61,797, against for the year 1909 £59,099, an increase of £2,698. Messages show an increase of £4,483; but, on the other hand, the sum received from the Portuguese Government in respect of the guarantee was reduced by £5,071, thus far showing a deficit, as compared with the preceding year, of £588. However, the loss on exchange is, I am happy to say, £2,504 less for 1910 than 1909, and to this should be added £782, representing the increase in interest on investments and cash at bankers, the net result of the year's working being an improvement in the revenue of £2,698. Turning to the expenditure side of the account, it will be seen that the total of the ordinary expenses for the year 1910 was £20,923, as against for the year 1909 £22,257, or a decrease of £1,334—a result almost entirely due to a reduction in the expenses attending maintenance of cables. Your directors recommend the payment of the usual dividend of 4s. per share for the half-year, making, with the previous payment, 4 per cent. for the year, and that the sum of £31,000 be added to reserve. This is the last year we shall be able to add so large a sum to the reserve, for the reason that, as I stated last year, the Portuguese guarantee ceases during the current year. However, our reserve fund now stands at the respectable figure of £268,428, but it must be borne in mind that, although the fund is invested in first-class securities, there is a considerable depreciation in the market value of the various stocks. I now move the adoption of the report and accounts and the declaration of the dividends.

The MANAGING DIRECTOR (Sir John Denison-Pender, K.C.M.G.), seconded the motion, which was carried unanimously.

The retiring director and auditors were re-elected, and a vote of thanks to the chairman, directors and staff terminated the proceedings.

Western Telegraph Co. (Ltd.)

The seventy-fifth ordinary general meeting was held on Wednesday, under the presidency of Sir JOHN WOLFE BARRY, K.C.B.

The SECRETARY (Mr. E. Steer Hodson) read the notice calling the meeting and the auditors' report.

The CHAIRMAN said: The revenue for the half-year ended Dec. 31 last, compared with the same period for 1909, increased by nearly £46,000, but a diminution in the amount of interest on investments, &c., reduced this by about £5,500, leaving a net increased revenue of about £40,500. The reduced amount of interest was consequent upon the sale of reserve fund investments during the year 1910, which represented a cost value of £360,060. These sales were necessary to meet payments for new cables, &c. The increase in traffic receipts was derived from all the countries served by the Company's system. On the other hand, there was an increase in the general expenses at the stations and the maintenance of cables and in the expenses of the repairing ships amounting in all to £22,000. The increased expenditure at the stations was caused by additional staff, to meet increasing traffic, by annual promotions, and by the enhanced value of the Brazilian currency.

When we had the pleasure of meeting the proprietors in November last I referred to the charter of the cable steamer "Cambria" to enable our own steamer "Norseman" to come to England for survey and repairs. The latter vessel has now been on cable work for nearly 25 years, and on examination it is gratifying to say that the deterioration was much less than might have been expected. The overhaul, repairs and installation of wireless telegraph apparatus, &c., cost £7,500. After providing £16,373. 10s. for debenture stock interest and £7,697. 9s. 10d. for income tax, there remains a balance of £245,142. 11s. 6d.; to this is added the sum of £7,512. 18s. 8d. brought forward from June 30 last, making a total of £252,655. 10s. 2d. First and second interim dividends, amounting to £62,379, have been paid, and after transferring £150,000 to the general reserve fund, and £10,000 to the land and buildings depreciation fund, there remains a balance of £30,276. 10s. 2d., which is carried forward to the next account. The revenue for the current period to date compares satisfactorily with former years, but a few weeks ago a reduction of 75 centimes per word in the tariff with Brazil was made, and a considerable increase in traffic will be required to recoup us for the reduction in the charges for telegrams.

The cable between St. Vincent (Cape de Verde) and the island of Ascension, to which reference was made at the last meeting, was successfully completed on December 26 last, and is a valuable addition to the means of communication with South America. It is right to note that we have now a new competitor in South America, for the German cable between the Canary Islands, West Africa and Pernambuco was opened in March last, but sufficient time has not yet elapsed to enable us to ascertain the effect of this competition. No further progress has been made since our last meeting with regard to the projected cable between the island of Ascension and Rio de Janeiro, but we must be prepared to carry this out at short notice, and the estimated large expenditure would, of course, have to be met out of the reserve fund.

Touching the position of our reserve fund, I may point out that in the last few years our great enterprise of laying a direct cable from St. Vincent to Argentina has necessitated an expenditure of about £950,000 and that there can be no doubt that in a similar manner we shall have, though at less expense, to strengthen our communication with Brazil whether it be via Rio direct or Pernambuco. Such demands as these on the resources of the Company are very heavy, but they are demands which must be met, if on the one hand we are to maintain our cable service in a condition to be adequate to our responsibilities to the public and so to ensure as far as possible the stability of our dividends and the steady value of our shares. It is facts such as these that alone abundantly justify the policy of the Board in placing large sums to our general reserve. But we have also to remember that the replacement of our existing cables as they become old—a matter dependent, as it must be, on circumstances beyond our control—will always necessitate the expenditure of money at periods and to an extent which cannot with any certainty be foreseen. Such expenditure, when it amounts to anything beyond ordinary maintenance, could not be charged against revenue without causing violent fluctuations in the amount available for dividend or else it would necessitate the periodical raising of fresh capital, which might be most inconvenient besides being bad in principle. Any such state of things could not be advantageous to the stockholders and would compare prejudicially with the practically stable dividends and steady price of our shares to which we are proud to point as having existed for so many years. These views are, of course, not new, but I have lately received from some valued shareholders letters urging on us the opposite policy of paying larger dividends and contributing less to the reserve fund. As their criticisms affect not merely their own but the interests also of the whole body of shareholders, I have thought it right now to make the above observations on the well-considered policy of your Directors, which has been from time to time emphatically endorsed at several of our general meetings and which I venture to think will once more commend itself to your judgment. I now move the adoption of the report and accounts.

The DEPUTY-CHAIRMAN (Sir John Denison-Pender, K.C.M.G. seconded the motion, which was carried unanimously.

There being no further business, a hearty vote of thanks to the chairman and directors brought the proceedings to a close.

West Coast of America Telegraph Co. (Ltd.)

The fourteenth ordinary general meeting was held on Tuesday, under the presidency of Sir JOHN DENISON-PENDER, K.C.M.G.

The SECRETARY (Mr. Frederick L. Robinson) having read the notice calling the meeting and the auditors' report,

The CHAIRMAN said: Gentlemen, our capital remains the same as last year. The receipts for 1910, £51,217, against £50,416, show a balance on the right side of some £800; and considering that the rate, which was reduced in 1909 from 5s. 9d. to 4s. 2d., was again reduced in the middle of 1910 to 3s. 7d., I think this is a satisfactory state of affairs. The working expenses in 1910 amounted to £39,357, compared with £39,204 in 1909, thus showing an increase of some £150. But we have decreases in travelling expense of £280, in medical expenses of £145, and in maintenance of cables and land lines £513. This, therefore, leaves us a balance on the right side as regards expenses. However, we must not forget that the chief saving, compared with the former year, was £513 in the maintenance of cable and land lines. This is, of course, always a varying amount, according to the number of repairs that have to be carried out by the ships and the extent of cable which has to be used in the repairs. The amount is, therefore, of a very fluctuating character from year to year. It is satisfactory to see that the reserve fund has now assumed the figure of £68,192, to which we can also add the ship's reserve of £5,000; but this reserve, when you come to think of the debenture debt and the income bonds, which amount together to £170,000, is after all not large, although the £170,000 is represented to a very considerable extent by cables and good assets. The only other point which I need mention, I think, is the laying, since our last meeting, of the Western Company's new cable from Ascension to the Argentine and the new German cable, which has been opened for about a month from the West Coast of Africa, where it connects with Europe, to Pernambuco. Those two cables ought to bring us a certain increase of traffic and although the new German cable will, to a certain extent, compete with our good friends, the Western Company, it will also, as far as the Company is concerned, possibly attract some of the traffic which has been across the Atlantic and down the West Coast; so we may, to a small extent, benefit by it. I have nothing else to point out to you, and I move that the report and accounts be adopted.

Mr. F. A. JOHNSTON seconded the motion, and it was carried unanimously, as were also resolutions approving the dividends, re-electing the retiring director and auditors, and according a hearty vote of thanks to the chairman and directors.

Submarine Cables Trust.

The fortieth ordinary annual meeting was held on Thursday, under the presidency of the Most Hon. the MARQUESS OF TWEEDDALE, K.T.

The SECRETARY (Mr. Sidney Collett) read the notice calling the meeting.

The CHAIRMAN said: The revenue for the year ended April 15 last after deducting the necessary working expenses, amounted to £24,0 to this had to be added the sum of £175 brought forward, making in an available balance of £24,208, as against £24,328 in the previous y or a difference of £120. This diminution is more apparent than real, is due to the fact that the last quarterly dividend on the shares of Central & South American Telegraph Co.—usually received before close of our financial year—did not reach us until after April 15. have paid the half-yearly coupons on Oct. 15 and April 15 last at the of 6 per cent. per annum net, absorbing £17,583. This left us wi surplus of £6,625, which, in accordance with the terms of the trust d we have used in the acquisition of 55 certificates; 34 of these were chased in the open market at 119-¼, and as we were unable to acc any more in that way, a further 21 were drawn by lot on the 4th ins

Digitized by Google

£30 per certificate. We have thus acquired out of the revenue for the year under review 55 certificates, which have absorbed £6,578, leaving a balance of £46 to be carried forward to the next account. This is the largest number of certificates we have acquired in any year out of the earnings of the trust. We have now acquired and cancelled 1,315 out of the original 4,200 certificates. I now move the adoption of the report and accounts.

Sir JOHN DENISON-PENDER, K.C.M.G., seconded the motion, which was carried unanimously.

The retiring auditors were re-appointed, and a vote of thanks to the chairman brought the proceedings to a close.

West India & Panama Telegraph Co. (Ltd.)

The sixty-eighth ordinary general meeting was held on Wednesday under the presidency of Mr. WALTER BISHOP KINGSFORD.

The MANAGER and SECRETARY (Mr. R. T. Brown) having read the notice calling the meeting and the auditors' certificate,

The CHAIRMAN said: The half-year under review has been an unsatisfactory one. I think you will agree with me that my forecast at our last meeting has been amply borne out by the results submitted to you in the report and accounts now in your hands. As you will have seen, the total income for the half-year is £40,306, or £5,628 more than the corresponding period to December, 1909, with which we are comparing. This substantial increase, all of it arising from traffic, is the more satisfactory, coming as it does in a December half-year, which with us is invariably the most serious half-year, or, as we usually term it, our "lean" half-year. On the expenditure side of the account it appears that the total of £34,919 is £762 in excess of that for the corresponding period of last year. In this, however, is included a sum of £386 for income tax on the increased dividend on the ordinary shares, and as that item did not occur in the corresponding half-year, it ranks now as an increase in our expenditure. In effect, therefore, the increase in our working expenses for the half-year is only £376. At our last meeting I referred to the establishment of the oil industry in the important colony of Trinidad, and I spoke favourably of the benefit likely to accrue from it to our Company. A proposal is made by the Consolidated Gold Fields of South Africa to acquire some of the oil lands of the General Petroleum Co., and other interests of oil lands in Trinidad, in a new undertaking with a capital of £1,250,000. It is said that no enterprise of such magnitude has ever been projected in that island. Should it be carried through successfully it is only reasonable to anticipate that our Company's business in the island would be materially benefited. Our cables, I am much pleased to say, are in perfect working order, and I am also very glad to be able to state that the receipts for the current half-year show a satisfactory increase. I now move the adoption of the report and accounts, and the payment of the preference and ordinary dividends set out therein.

Mr. HENRY HOLMES seconded the motion, which was carried unanimously.

A discussion ensued as to a vote for the directors' remuneration, after which the retiring director, Mr. Henry Holmes, was re-elected, as were the auditors. A very hearty vote of thanks to the chairman, directors and staff at home and abroad terminated the proceedings.

BERGMANN ELEKTRICITATS GESELLSCHAFT.—At the recent meeting of the company at Berlin it was stated that the cost of the proceedings undertaken in the English courts as to the metal-filament lamp patents amounted to 150,000 marks. During the past two years their automobile department had been worked at a loss, but prices were now much better, and large orders in hand for 900 to 1,000 cars, the greater proportion for the English market. They had obtained a 10 years' contract for the supply of machines to the recently-formed subsidiary C. Lorenz Co., the Frankfort Machine Co., and they considered that the patents would have far-reaching effects on the commercial development of wire-drawing.

CALCUTTA ELECTRIC SUPPLY CORPN. (LTD.)—During 1910 8,940,005 units of electrical energy were sold, compared with 7,856,383 in 1909. The number of houses connected at Dec. 31 last was 5,695 compared with 5,078, and the equivalent connections in 8 c.p. lamps show an increase of 56,066. The profits amount to £85,597. 15s. 5d., and, after paying an interim dividend at rate of 7 per cent. per annum there is, including £58,366. 3s. 11d. brought forward and interest, a balance of £58,366. 3s. 11d. The directors recommend that £20,000 be placed to credit of depreciation and renewals account, that £7,500 be added to reserve and that a final dividend be paid at the rate of 10 per cent. (making 8½ per cent. for the year), which will leave £5,621. 13s. 7d. to be carried forward. The additional plant in the Ultadangha station, as recommended by the consulting engineer, has been duly installed, the high-tension mains laid and the supply to the jute presses in the Northern district commenced in September. The arrangements for the establishment of a new generating station in the Cossipore district are well advanced, and the first portion of the work is expected to be completed next year. The meeting was with regret to the recent death of the chairman, Mr. Edmund Vincent.

CORK ELECTRIC TRAMWAYS & LIGHTING CO. (LTD.)—At the meeting Mr. A. R. Monks said that owing to the increased popularity of metal filament lamps due to the great economy of metal filament lamps, there was a substantial increase in the number of consumers, representing 1,500 lamps. The demand for electricity for power showed no falling off. Their lighting and power revenue for the past year showed an increase of £1,500, and the additional connections obtained during 1910 and 1911 connections obtained since Jan. 1 should result in a further improvement for the current year. The District Council lighting he had previously referred to had been completed. The Council had increased the number of public lamps originally contemplated. They had recently installed, owing to increased demands, an additional boiler, with mechanical stoker and superheater. The traffic receipts were satisfactory, and there was an increase in the takings of £2,054. The total revenue showed an increase of £3,337, and as there was only an increase of £576 in expenses, the gross profits show an improvement of £2,761. The increase in expenses was in connection with the traction side of the business, and was due to heavier maintenance charges for track and rolling stock. They had written £1,772 off house services, wiring consumers' premises, plant on loan, &c., and had transferred £5,000 to reserve for depreciation. They were increasing the dividend to 4 per cent.

DELHI ELECTRIC TRAMWAYS & LIGHTING CO. (LTD.)—Col. Sir Buchanan Scott stated at the meeting on Tuesday that an amicable settlement had been arrived at with the contractors of all their claims in connection with the works contract. The business showed continued increase, particularly with regard to the tramways, which were now showing a profit. The number of power consumers was increasing, and the company was able to undertake contracts on more favourable terms.

ELECTRIC SUPPLY CORPN. (LTD.)—The gross earnings during 1910 amounted to £25,466, an increase of £1,665 over the corresponding period of 1909. Net revenue account amounts to £11,224 against £9,300. After paying interest, £4,774 remains, compared with £3,780. This account has been debited with £814, the actual cost of the year's repairs and renewals. The directors propose to utilise the surplus of £3,960 by placing £500 to renewals account, by writing £1,248 off expenditure on temporary plant and the cost of transferring the Hendon undertaking, leaving £2,212 to be carried forward. During the year 2,479,172 units were sold, against 2,492,416 units in 1909, and there was an equivalent of 135,719 32-watt lamps connected to the mains of the various undertakings of the Company, against 113,699 in 1909.

JOHNSON & PHILLIPS (LTD.)—The report for the year to Dec. 31 states that the profit on trading accounts, &c., after making provision for bad and doubtful debts, and after charging to revenue upwards of £5,337 for maintenance of buildings, plant, &c., amounts to £23,175, with balance brought forward (£942) the amount available is £24,117. Deducting remuneration of directors, auditors' and trustees' fees (£1,563), interest on debenture stock to Dec. 31 (£7,473), reserve *re* debenture sinking fund (£5,438), interest on second debentures (£1,488), depreciation on machinery and plant, &c. (£4,500) and amount written off investments (£1,500), there is a balance of £2,154 to carry forward. The business during the year has shown considerable improvement, and the profit shows an increase of £7,815 over 1909.

HONG KONG TRAMWAYS CO. (LTD.)—The report for 1910 states there was a considerable increase in gross traffic receipts (£3,564), but the net traffic receipts show an increase of £764 only, the difference being due to a further shrinkage in the values of the subsidiary coinage. After careful consideration it has been decided to charge an additional cent for every five-cent fare paid in Chinese copper coins. The working expenses show a decrease of nearly £1,500. After providing for working expenses and payment of debenture interest, there is a profit of £7,988, which, added to amount brought forward, makes £8,557, which is carried forward; £10,000 is to be expended on permanent improvements or additions to the property before payment of any dividend.

LISBON ELECTRIC TRAMWAYS (LTD.)—The result of the operations for the past year shows a net profit of £107,425, added to £481. 13s. 8d. brought forward, making £107,906. 13s. 8d. From this £35,000 has been placed to depreciation reserve and £5,000 to credit of exchange reserve, leaving an available balance of £67,906. 13s. 8d., out of which preference dividend (£25,533. 3s. 8d.) has been paid. An interim dividend of 3 per cent. net (£19,020. 15s. 7d.) was paid on the ordinary share capital, and the directors now recommend payment of a final dividend of 2½ per cent. net (£15,850. 13s.), making 5½ per cent. for 1910; £7,502. 1s. 5d. has been carried forward. Previous to the revolution in October, the traffic showed a considerable increase over former years; since then this expansion has been arrested, and during the period of conflict the operations were completely suspended. After the establishment of the Provisional Government, the employées formulated demands which could not be conceded, and in consequence a strike took place. The company thought it wise to request the arbitration of Dr. Antonio Jose d'Almeida, Minister of the Interior, and the points of difference between the company and its employees were finally settled by his award.

MANILA ELECTRIC RAILROAD & LIGHTING CORPN. (LTD.)—The report for 1910 states that there was an increase in gross earnings over 1909 of $175,340, in operating expenses of $10,588 and in net earnings of $164,751. The apparently abnormal increase in net earnings was largely due to the strike of 1909. The directors have declared four quarterly dividends of 1 per cent. each, leaving $144,356 which had been transferred to surplus account. In order to handle the increase in business the directors authorised the purchase of one 2,500 k.v.a. steam turbine and alternator, with auxiliaries, which should be ready for service by the end of the year.

The Philippine Islands are developing industrially at a rapid rate.

Since the beginning of the current year the dividend rate has been increased from 4 to 5 per cent.

RANGOON ELECTRIC TRAMWAY AND SUPPLY CO. (LTD.)—The directors' report for 1910 states that the new power house has been completed and is now ready to receive the 2,500 kw. turbine, which has arrived at Rangoon. During the year 1,472,471 car-miles were run, an increase of 13,008, and 9,281,817 passengers were carried, against

Digitized by Google

9,308,674, the receipts being Rs8,79,245, an increase of Rs2,258. There had been a steady increase in the private lighting and power department. Receipts were Rs2,91,183, against Rs1,98,233, an increase of over 46 per cent., while working expenses were 51·13 per cent., against 64·08 per cent. Gross profits were £46,177 (compared with £45,170 for the 13 months ended Dec. 31, 1909). The directors recommend a dividend on the ordinary shares of 4 per cent. for the year, tax free, carrying forward £822.

REUTER'S TELEGRAM CO. (LTD.)—The directors' report for 1910 states that the balance for distribution amounts to £5,229. 13s. 3d., including £256. 14s. 9d. brought forward. An interim dividend of 2½ per cent. was paid in October and the directors now declare a dividend of 4s. per share, 2½ per cent., making a total distribution (tax free) of 5 per cent. for the year, and leaving £494. 1s. 3d. to be carried forward.

SINGAFORE ELECTRIC TRAMWAYS (LTD.)—The accounts for 1910 show an excess of revenue over expenditure of £31,013. 12s. 1d., the profit for the year, after charging debenture interest, depreciation and royalty being £1,843. 12s. 11d. Compared with 1909, tramway revenue shows an increase of £3,622. 15s. 6d. There were 268,332 more passengers carried and 14,502 more car-miles run, the latter mainly due to the completion of an additional section of route. The number of passengers carried per car-mile has risen from 5·96 in 1909 to 6·04. The revenue from lighting and power supply shows an increase of 38 per cent.

At the meeting on Tuesday Sir FRANK A. SWETTENHAM, K.C.M.G., said there was a considerable increase in the Singapore receipts, but the ratio of working expenses to receipts had risen slightly, being 53 per cent., against 52·3 per cent. The revenue from lighting and power supplies showed an increase of 38 per cent. The increase was the more satisfactory, as during 1909 the company had a large demand for energy from contractors at that time working in Singapore, which demand did not continue into 1910. The Anderson Bridge over the Singapore River, which was opened on March 12 of last year, had increased the receipts for the year by about $20,000.

SWANSEA IMPROVEMENTS & TRAMWAYS CO. The report for 1910 states that the total revenue on the tramway undertaking for the year amounted to £59,308, an increase of £5,769 over 1909. Traffic receipts were £57,469, increase £5,530. Deducting expenses, and including interest, and amount payable to Swansea Corporation on lease account, and after charging £6,000 for renewals, the surplus was £11,285, making, with £1,211 brought forward, £12,496. The directors recommend that £3,000 be placed to depreciation and reserve and after providing for the preference dividends a dividend on the ordinary shares of 4½ per cent. for the year is recommended, leaving £1,047 to be carried forward. Capital expenditure during the year amounted to £1,959. There was also expended £2,321 on renewals of permanent way, electrical equipment and plant, which was charged to the provision for renewals account. During the year the Company paid £2,000 to the British Electric Traction Co. in reduction of the liability in respect of advances for reconstruction. The net profit on the Mumbles Railways and Pier was £1,107, and was payable to the British Electric Traction Co. for interest on moneys provided by them.

VERA CRUZ ELECTRIC LIGHT, POWER & TRACTION (LTD.)—At the meeting on Wednesday Mr. V. W. Yorke said the increase in the various sections of the business had been steadily maintained, while working expenses had been gradually reduced. The question of the provision of additional power to cope with the growing demand had been receiving the attention of the board, and negotiations were now being carried on for a supply of water power.

The net profits in Mexico for 1910 were £24,107 compared with £19,043 for 1909. The balance (including sum brought forward) amounts to £10,293, which it is recommended should be carried forward.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES, &c,

NEW COMPANIES.

BRITISH AMERICAN TRADING CO. (LTD.) (115,579.)—Reg. May 2, capital £100 in £1 shares, to carry on the business of railway, electrical engineering and machinery contractors, agents, &c. Private company. E. E. Griffiths permanent governing director. Reg. office: 7, Idol-lane, London, E.C.

CHARLES HASELER & SON (LTD.) (115,683.)—Reg. May 8, capital £1,000 in £1 shares, to take over business carried on by C. E. Haseler at Birmingham, and to carry on the business of electricians, mechanical engineers, founders, dealers in electricity, &c. Private company. First directors: W. Izon (chairman), C. E. Haseler and C. Lacey. Reg. office: 94, Bridge-street West, Birmingham.

KAI-BITUM PAINT CO. (LTD.) (115,533.)—Reg. April 29, capital £2,500 in £1 shares, to take over the business of the sale of paint, lacquer and glue hitherto carried on by Callender's Cable & Construction Co. (Ltd.) Private company. Reg. office: Belvedere, Kent.

J. MARSE & CO. (LTD.) (115,771.)—Reg. May 11, capital £1,000 in £1 shares, to carry on business of electrical, mechanical and general engineers, founders, &c. Private company. Reg. office: Imperial Buildings, Ludgate-circus, London, E.C.

SPELMONT GAS & ELECTRIC GENERATOR SYND. (LTD.) (115,677.)—Reg. May 6, capital £5,000 in 40,000 preference shares of 2s. each and 1,000 deferred shares of £1 each, to carry on the business of manufacturers of and dealers in machines or apparatus for the production or generation of gas or electricity, &c., and to adopt an agreement with S. P. Eastick. Private company. Reg. office: 71 & 72, Strand, London, W.C.

VENNER TIME SWITCHES (LTD.) (115,468).—Reg. April 26, capital £7,000 in £1 shares, to acquire and turn to account certain inventions relating to improvements in or relating to electrical time switches, &c., and to adopt an agreement with R. F. S. Venner, R. C. Griesbach and E. E. Sharp. Private company. First directors: R. F. S. Venner, R. C. Griesbach and E. E. Sharp (all permanent, subject to holding 150 shares). Reg. Office: 6, Old Queen-street, Westminster, S.W.

MORTGAGES AND CHARGES.

ELECTRICAL FITTINGS CO. (1911) (LTD.)—Debenture dated April 28, 1911, to secure £5,000 and 5 per cent. interest, charged on company's undertaking and property, present and future. Holders: Samuel Heath & Sons.

ELECTRICAL INSTALLATIONS (LTD.)—Memorandum of satisfaction to the extent of £450, on Jan. 16, 1911, of debentures dated Dec. 5, 1906, securing £2,000, has been filed.

ESCARE & DENELLE (LTD.)—Particulars of £6,000 debenture stock created April 14, and secured by trust deed of even date, has been filed, amount of present issue being £3,900. Property charged: leasehold premises and company's undertaking and property, present and future. Trustees: R. T. Smith and H. Samson.

FLOAT ELECTRIC CO. (LTD.)—A second mortgage debenture, dated April 10, 1911, to secure £7,000, charged on company's undertaking and property, present and future, including uncalled capital (subject to first debenture for £2,800) has been filed. Holder: C. J. V. Blundell.

PAIGNTON ELECTRIC LIGHT & POWER CO. (LTD.)—Particulars of £5,000 in debentures, created Nov. 23, 1910, have been filed, the amount of present issue being £2,000. Property charged: company's undertaking and property, present and future, including uncalled capital. No trustees.

TRACTION SUPPLIES CO. (LTD.)—Particulars of £1,000 debenture created Nov. 15, 1910, have been filed, amount of present issue being £600. Property charged: Company's undertaking and property present and future. No trustees.

CITY NOTES.

MEMORANDA (May 18).—**Bank rate 3 per cent.** (March 9, 191 **Price of silver,** 24⅜d. per oz. Consols 81⅛—81⅜ for money and account. NOTES.

The Policy of the Post Office.

The statement of the Postmaster-General last week in introducing the annual estimates, as reported in our present issue, is of more than usual interest. Although it does not go so far as to include Mr. Henniker Heaton's scheme of penny-a-word telegrams throughout the Empire, it nevertheless bears striking testimony to the ready way in which the cable companies reduce their rates when any reasonable ground can be shown for doing so. Mr. Samuel stated that he considered the cable companies were entitled to much credit for their readiness to listen to representations in this direction. They have, in fact, consented to a large reduction in the rates charged for plain-language telegrams of the non-urgent character, such reduction amounting to 50 per cent. This will appeal to the ordinary user as distinct from those who conduct urgent business telegraphically, and should certainly lead to an increase in the number of long-distance messages. It is also interesting to note that the number of ships fitted with wireless apparatus has increased during the past year from 130 to 290, and that the number of "Marconigrams" has increased 60 per cent. In regard to the telephone policy of the Post Office the most interesting announcement is that an endeavour is to be made to develop a system of rural telephones similar to that in America, an unlimited use of the telephone being given for £3 per annum to any farmer who is willing to join with four of his neighbours in a "party" line. This is certainly a cheap service, and it assumes, no doubt, that the needs of the farmer, telephonically speaking, are comparatively few. Our experience, however, is that the use of the telephone rapidly increases as the subscriber comes to learn its convenience, and for this reason it would seem that the rate proposed may have to be revised from time to time, or a restriction placed on the number of calls per day per party-line subscriber.

London County Council Tramways.

The present and future position of their tramways was under discussion by the London County Council for some hours on Tuesday last when the Highways Committee presented a report on workmen's cars and estimates for the financial year 1911-1912. As regards the past year, the revenue from the tramways exceeded the working expenses by £900,885, but as the capital charges amounted to £706,481 there was only £49,574 to place to the reserve fund after a sum equivalent to ¾d. per car-mile had been set aside for renewals in accordance with the policy adopted a year or two ago. The present position must have come as a surprise to a large proportion of the Council, and, in view of the fact that the Highways Committee anticipate a smaller surplus from the trams next year, Sir John Benn's description of the present position as a crisis in the history of the undertaking is certainly not wide of the mark. In fact, a decrease of £56,000 in the surplus from the electric lines is estimated. The main complaint appears to be that, whereas the Council have to contribute £118,000 per

Digitized by Google

annum for road maintenance, the competing omnibuses are not handicapped in this respect. There is no doubt that the position is unfair to the tramways, and the directors of the tube railways have also drawn attention to the favoured position of the motor-omnibus companies. As the whole question has recently been brought into prominence, the advantages of the omnibus being unduly lauded in leading articles in the "Daily Mail," it is to be hoped that if there is to be competition between the various traffic concerns such competition will be on an equitable basis. It must not be forgotten, however, that the capital expenditure with which the tramways are saddled would probably have stood at a much higher figure if the work had been carried out by a company, since doubt has been expressed as to whether the undertaking has been debited with its fair share of the cost of street improvements, &c.

In connection with the report presented by the Highways Committee it is interesting to have it placed on record that the workmen's fares were responsible last year for a loss of £61,302 on the electric cars, or almost 40 per cent. of the revenue received from these fares, the deficiency including a sum for capital charges and provision for renewals: on the horse cars the corresponding loss was £4,630. As a matter of fact, however, the deficiency is greater than that mentioned, as the working expenses, in making the estimate, were based on the average of the whole operation of the system, whilst really they are greater on the workmen's cars. Under these circumstances it is not surprising that the Committee considered it would be extremely unwise to extend the hours during which such cheap tickets are issued; and they also reported against proposals for granting additional facilities, such as special fares for children and working women.

The Telephone Authority.

At the eleventh hour, when the final arrangements were being made for the transfer of the telephone system in this country from the National Telephone Co. to the Post Office, Mr. Laws Webb came forward with a fresh proposal, a proposal intended to prevent the introduction of another State monopoly. His argument in favour of the telephone system of the country being carried on in future by means of a Telephone Authority has been supported both by the London Chamber of Commerce and by the Associated Chambers of Commerce; in other words, by the business men of the country. The proposal has, in fact, been so well received that the Post Office has thought it worth while to come out into the open and advance arguments on the other side. Both the Postmaster-General and Mr. John Lee have laid great stress on the benefits which will result from the telephones passing under Government control, but they are not able to explain away the undoubted disadvantages of such a transfer.

Further arguments, from what may be called the telephone user's point of view, were advanced by Mr. Faithfull Begg in an address which he delivered before the London Chamber of Commerce last week. He pointed out that the expenses of working the Post Office telephones have always been higher than those obtained by the Telephone Company, while the way in which the accounts are kept in the Government department makes it impossible to tell exactly how things stand. Further, the boasted increase in trunk facilities made during the time these lines have been under Post Office control, is by no means so great as it ought to have been.

In our opinion, every effort ought to be made to prevent the telephones from passing into the control of the Post Office; and we are, therefore, glad to see that Mr. Laws Webb's proposal has received such a large measure of support in so short a time. A telephone system worked by the Post Office will always tend to inefficiency owing to the very nature of the conditions. Further, the pressure brought to bear by organised labour will be certain to cause the service to deteriorate, with the result that facilities will be lessened and, even if the rates are lowered, there will be no compensation for the great disadvantage of not having the telephone always available in country districts, or for its inefficiency when one can use it. As an example of what may be expected from Post Office control, we may instance the practice of closing country telegraph offices on certain afternoons in the week. A telegram may be sent to some one in the area served by the closed office; it is dispatched by messenger from another office farther away and porterage is charged. Thus, not only are the facilities made unavailable, but the public are made to pay for their unavailability. In our opinion, the telephone and telegraph services ought always to be "on tap" wherever they are installed; but if the Post Office obtain control of them there does not seem much chance of this. There is one further point; even if the Post Office were desirous of extending the telephone system at an adequate rate they would be handicapped by the Treasury. The public money is at present ear-marked for much more highly coloured schemes than developing the telephone.

Invisible Light.

Prof. R. W. Wood's Friday evening discourse at the Royal Institution last week was of interest as showing certain possibilities in working with the invisible parts of the spectrum. When it is remembered that if the visible spectrum is represented by half a yard the total spectrum has a length of 500 yards, it can be seen what a very large ground there is in which rays of some utility may exist and might perhaps be usefully employed. By proceeding towards the lower limit we come very near electric waves. Heat waves $\frac{1}{2}$ mm. in length have been isolated by Rubens, whereas the shortest electric wave that has been produced is about 2 mm., thus leaving a very small gap between the two kinds of radiation. Prof. Wood, however, was more concerned with the immediate infra-red and ultra-violet rays, and he showed some very interesting photographs taken by their means. In the infra-red photographs it was noticeable that these rays are reflected very strongly by foliage, giving the effect of bright sunshine, which is intensified by the blackness of the sky unless clouds are present. On the other hand, in ultra-violet photographs obtained

Digitized by Google

by a quartz lens covered with a thin film of silver, there is an almost entire lack of shadow, and there are also some other marked differences; for example, Chinese white appears black by ultra-violet rays. Results of this kind induced Prof. Wood to take ultra-violet photographs of the moon, and in these he found certain dark patches which were not present in photographs taken with ordinary light. This indicates that the crust of the moon contains certain rocks which are dark to ultra-violet rays. Thus we are able to obtain further information than has hitherto been possible as regards lunar constitution, though it is impossible at the present time to identify the rocks, as there may be many materials which would be capable of producing such a result.

Earth Currents.—We have received a letter from Mr. W. R. Rawlings in which he mentions a case of fusion of pipes by earth currents. The pipes in question were an iron gas pipe, and a lead water pipe, both pipes being fused at the point of contact. Mr. Rawlings will be pleased to show the specimens to anyone interested in the subject.

"Imperial Telegraphs."—In reference to Mr. G. R. Neilson's letter of last week, Mr. Charles Bright points out that a large proportion of our readers not present at the meeting, and perhaps many miles away, in reading our necessarily condensed report would naturally have assumed that Mr. Neilson's remarks were in reply to him (Mr. Bright), and he wishes to explain that otherwise he would not have written in regard to Mr. Neilson's comment.

Oil Fuel for Steam Boilers.—At a recent meeting of the Boston Mechanical Engineers a Paper on this subject by Mr. B. R. T. Collins was read. A valuable feature of the Paper was the presentation of a series of tests made last autumn at the Redondo (Cal.) plant of the Pacific Light & Power Co. on a 500 h.p. Babcock and Wilcox boiler equipped with a Hammel furnace and burners. The boiler was in regular service under the usual operating conditions. The oil was obtained from the Los Angeles fields, with a heating value of about 18,300 units. A maximum efficiency of 83·3 per cent. was obtained on the tests while running at 109·2 per cent. of the maker's rating, and the water evaporated per pound of oil from and at 212°F. corrected for moisture was 15·81 lb. The average efficiency for seven tests was 80·47 per cent., and the average evaporation 15·29 lb.

Railway Electrification in Prussia.—As the result of the successful experiments which have been carried out with electric traction between Dessau and Bitterfeld on the Prussian State Railways, the Berlin correspondent of "The Times" reports that the Diet is now asked for fresh credits to the amount of £1,366,500—being £871,500 for further work on the Magdeburg section, and £495,000 as a first instalment of the cost of electrification of the section Laubau-Dittersbach-Königszelt, with a number of small branches, in Silesia. The Prussian authorities point out that the electrification of main lines has become a financial possibility with the adoption of alternating current, and while electric traction is held to be in many ways preferable for the railways themselves, great importance is attached to the subsidiary use of the electric installations for industry and agriculture, as well as for lighting and heating. It is, however, held to be uncertain whether electric traction will meet military requirements, and there will, therefore, be no electrification for the present of strategic railways or of lines which are of strategic importance.

Cable Interruptions.

	Date of Interruption.
Aseab–Perim	July 8, 1909
Malta–Tripoli	April 20, 1910
Latakia–Palura	May 26, 1910
Tourane–Amoy	Sept 25, 1910

Combination Baggage Car and Snow Sweeper.—The "Electric Railway Journal" states that the Michigan United Railways Co. has recently equipped at its Albion shops two large snow sweepers. Each of the new machines is so constructed that it may be used during the winter months as a snow sweeper and converted for use as a baggage car during the summer. As the Michigan United Railways electric system includes about 80 miles of third-rail track, provision is made for operating either with third-rail or trolley current collectors, and small brooms are also provided for cleaning the third-rail. These brooms are mounted on extensions of the main broom shaft. Each of the new cars is equipped with four motors. The brakes are supplied from an air compressor and the brooms are operated by motors.

"The Electrical Equipment of a Modern Theatre."—Messrs. J. P. Hall & Co. point out that in the article by Mr. D. C. M. Hume on this subject which appeared in our last issue it is stated that the controllers and motors at the London Coliseum were supplied by the Sturtevant Engineering Co. Messrs. Hall inform us that the motors were manufactured by them, the controllers being supplied by the Sturtevant Engineering Co. to their order.

Sir John Wolfe Barry, K.C.B., F.R.S.—A complimentary dinner was given last week in the hall of the Worshipful Company of Goldsmiths, Foster-lane, London, E.C., to Sir John Wolfe Barry as initiator and chairman of the Engineering Standards Committee. An illuminated address was presented. Sir W. H. White proposed the health of Sir John and referred to the great work which had been accomplished by the Committee over which he presided and its effect upon the extension of the trade of the Empire. In reply Sir John said that the results of the work of the Engineering Standards Committee had been fully recognised by engineers and manufacturers, the chief Departments of the State and other public authorities. The manufacturing and trading interests of this country had been greatly enhanced by the Committee's labours, and the cost of production had been materially reduced. The fact that the Committee was now permanently in session was a gauge of the importance of its work.

Forthcoming Books.—Messrs. E. & F. N. Spon announce the publication at an early date of a "Bibliographical History of Electricity and Magnetism," chronologically arranged by Paul Fleury Mottelay. The work will be divided into three parts. Part I. will cover the period from 2637 B.C. to 1799 A.D.; part II. from 1800 A.D. to 1820–21 A.D.; and part III. will consist of two appendixes giving accounts of early writers, navigators and others referred to by Gilbert in his "De Magnete," of discoveries made by Gilbert, and a general index. The book will contain of about 600 pages.

The Cambridge University Press will shortly issue (both in the series of Cambridge Manuals of Science and Literature) "Aerial Locomotion," by E. H. Harper, B.A., and Allan Ferguson, B.Sc., and "Electricity in Locomotion," by A. G. Whyte, B.Sc. Mr. Whyte gives a full account of the application of electricity to locomotion, and shows the present condition and the developments which may be looked for in the near future.

On the Absolute Measurement of Light.—A Proposal for an Ultimate Light Standard.—At a recent meeting of the Royal Society a Paper on this subject was read by Dr. R. A. Houstoun. The author stated that a thermopile could not be used for the measurement of candle-power because it gave the same value to the energy of every wave-length, invisible as well as visible. The author, however, had found by spectro-photometric investigation in the ultra-violet, visible, and infra-red parts of the spectrum that, if a filter consisting of aqueous solutions of copper sulphate and potassium bichromate of a particular strength in glass cells be placed before the thermopile, then this filter stopped the ultra-violet and infra-red entirely, and let through a fraction of each wave-length in the visible spectrum proportional to its visibility. In other words, it weighted each radiation according to its visibility. The voltage of a tantalum lamp was varied over a wide range, and its

Digitized by Google

candle-power as read by thermopile and filters agreed well with the readings of a photometer. Owing to the high sensitiveness of the galvanometer required the method was not suitable for commercial application, except perhaps for integration photometry when a number of thermopiles might be connected in series with the one galvanometer. The importance of the method lay in the fact that it provided a satisfactory basis for heterochromatic photometry independent of the Purkinje phenomenon at all intensities. The author therefore proposed to use it for defining the unit of light intensity. He would define the latter as that source, the total intensity of radiation from which at a distance of 1 metre after passing through his filters would be x ergs/square centimetre, seconds. For the standard candle x should be about 0·8.

"State Monopoly or Popular Control." —In an address on this subject which Mr. F. Faithfull Begg delivered before the London Chamber of Commerce last week the proposals of Mr. H. Laws Webb for the establishment of a telephone authority were further dealt with. The scope of the proposals, Mr. Begg said, had not been thoroughly understood. The Postmaster-General, for example, did not seem to be aware that a complete severance of the whole telephone service from the Post Office administration was proposed, or that the Telephone Authority was intended to be composed of experts in telephone business who would be responsible for the financial result; and at the same time financially independent of the Treasury. One main object was to secure that there should be no confusion between telegraph and telephone accounts, such as had occurred in the past in the Post Office Department, or that the present annual loss on telegraphs should be saddled upon the telephone revenue. The telephone in the past had never had fair play, the Post Office being always governed by fear of injury to the telegraph revenue. The Post Office working of telephones compared most unfavourably with the National Telephone Co.'s working, the former being worked at 74·4 per cent., as against 58 per cent. of the gross revenue in the case of the National Telephone Co. The Post Office earned 3·5 per cent. on its capital and the National Telephone Co. 8·9 per cent. The recent development of trunk wires in the United States had been nearly double that in the United Kingdom, while the increase in the number of stations was much greater in proportion. Basing the calculation on the rate of progress made in the United States, to make up the lee-way in this country, £116,500,000 would have to be spent during the next 10 years. The Postmaster-General had asserted that the separation of the telephone from the telegraph was physically impossible owing to the manner in which the plant was interwoven. This was, no doubt, the honest view of the Post Office officials. Experts thought otherwise, and as a matter of fact the Post Office and the National Telephone Co. were at the present moment mutually leasing overhead and underground wires to each other. There was really no practical difficulty which could not be overcome if a desire to overcome it existed. Moreover, the probable extension was so great that very shortly existing plant would form a small proportion of the whole. No answer had been made to the argument on the political aspect of the question. The telephone staff might easily grow to 100,000 in the near future, and in view of the present system of pressure upon Members of Parliament and others on the part of Post Office employés, this was an exceedingly grave question. In conclusion, the lecturer said he was convinced that unless some plan could be devised to prevent the absolute transfer of the telephones to the Post Office, the system must fall under the paralysing influence of State monopoly and development be arrested. Commercial interests were vitally affected by the question. It was almost impossible to exaggerate the importance of the problem. Keenness of modern competition rendered it necessary to provide every facility for business, and rapid communication was one of the most vital issues. In his opinion a Government department was wholly ineffectual for handling such an extensive, delicate and scientific problem, and the only satisfactory solution would be to establish a telephone authority representing all interests and popularly controlled, as advocated by the London Chamber of Commerce.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. D. C. M. Hume concludes his article on "The Electrical Equipment of a Modern Theatre."

Mr. Haydn T. Harrison contributes an article on "The Nomenclature of Primary and Secondary Sources of Light."

At the meeting of the Institution of Electrical Engineers last night Messrs. S. W. Melsom and H. C. Booth read a Paper on "The Heating of Cables with Current."

We conclude our abstract of Mr. W. Aitken's Paper on "Automatic Telephone Exchange systems," read at the meeting of the Institution last week. An account is also given of the discussion that took place. The subject of "Automatic Telephony" is considered in our leading article.

At a recent meeting of the Faraday Society Mr. A. Scott-Hansen read a Paper on "Hydro-Electric Plants in Norway and their application to Electromechanical Industries."

An interesting instrument, known as the "Ampall," has been placed on the market by Mr. R. W. Paul. This enables the current flowing in a circuit to be determined without interrupting the current for the purpose of inserting a shunt or ammeter in the circuit.

We describe a new system of motor car lighting which has been devised by Mr. Gavan Inrig. This is known as the "Carleon" system.

The Home Office have issued a Draft Order under the Mines Accidents (Rescue and Aid) Act, 1910, for the organisation of rescue and aid in cases of accidents in mines.

The Westminster Electric Supply Corporation opened on Wednesday last demonstration rooms at their main offices in Eccleston-place, S.W. An excellent collection of electrical apparatus has been got together, and considerable attention is being paid to the demonstration of the advantages of electric cooking.

Municipal Loans.—An inquiry has been held during the past week at *St. Helens* into the application of the Corporation for permission to borrow £10,800 for electricity supply purposes.—*Walthamstow* Council have applied for sanction to a loan of £5,149 for a feeder cable.—*Poplar* Council have applied to the London County Council for a loan of £42,455 for their electricity undertaking.—*Derby* Corporation made an application last week for power to borrow £8,500 for extensions of the electricity undertaking. There was an increase in the output during the last 12 months of over 913,000 units, bringing the total up to nearly 5,600,000.

Parliamentary.—In the House of Commons last week the Postmaster-General, Mr. H. Samuel, introduced the Post Office estimates for the current year, and made an interesting statement as to the progress of the postal, telegraph and telephone departments. He also announced a series of concessions, including some improvements in the postal service, the reduction of foreign parcel post rates, cheaper and improved cable communication, extended telephone facilities, &c.

On Friday last a House of Commons Committee passed the Birmingham Extension Bill, which authorises the Corporation to acquire control of some of the surrounding districts, with, *inter alia*, their tramways and electricity supply undertakings.

Select Committees of the House of Commons have also been considering during the week the Greater London Railway and the Newcastle-on-Tyne Corporation Bills, and Standing Committee B has made further progress with the Coal Mines Bill.

Legal.—A Divisional Court on Tuesday dismissed a motion by the British Westinghouse Electric & Manufacturing Co. to set aside an arbitration award in regard to an alleged breach of contract for the supply of turbo-generators to the Underground Electric Railways Co. of London. The applicants are taking the case to the Court of Appeal.

An interesting judgment on telephone agreements was given by His Honor Judge Scully at Brighton County Court last week.

Last week the First Division of the Court of Session, Edinburgh allowed the appeal of plaintiffs in the action brought by Johannesburg Municipal Council against Messrs. D. Stewart & Co. (1902), Ltd. (for damages for alleged breach of contract), from an order granting defendants further time to prepare their defence.

PERSONAL NOTE.

Mr. Geo. Tate, for 10 years works manager to Arc Lamps (Ltd.) informs us that he has severed his connection with the Company Communications for Mr. Tate should be addressed to 3, Blenheim road, St. Albans, Herts.

APPOINTMENTS VACANT AND FILLED.

An assistant lecturer and demonstrator in physics is required for University College, Nottingham. Applications by June 1 to the Registrar, from whom particulars can be obtained.

A demonstrator in physics is required for Durban (Natal) Technical Institute. Salary £300, rising to £400. Further information from W. A. Narbeth, Langford House, Eltham, Kent, to whom applications by June 7.

A demonstrator in physics is required for Armstrong College, Newcastle-on-Tyne. Salary £100 rising to £120. Applications to Mr. F. H. Pruen, Secretary, by June 23.

Mr. A. A. Dirks has now been permanently appointed as electrical engineer to the Post and Telegraph Department at Melbourne, in succession to Mr. H. W. Jenvey (retired) and Mr. T. Howard has been appointed manager of the telegraph branch, in succession to Mr. W. Radford.

Mr. F. E. Spencer (Melbourne) has been appointed electrical engineer to Redfern (Sydney) Council, in succession to Mr. J. Balfour.

Mr. J. E. Jinks, formerly traffic manager of Ballarat (Victoria) tramways, has been appointed superintendent of Launceston (Tasmania) tramways.

Mr. T. R. Stancombe, of Barnsley, has been appointed sales engineer to the Yorkshire Electric Power Co.

Mr. K. Bulpit has been appointed shift engineer at Barnes.

INSTITUTIONS AND SOCIETIES.

Royal Society.—The following Papers were read before this Society at their meeting yesterday afternoon: "Experiments on the Compression of Liquids at High Pressures," by the Hon. C. A. Parsons, F.R.S., and Mr. S. S. Cook; "Energy Transformations by X Rays," by Prof. W. H. Bragg, F.R.S. and Mr. H. L. Porter; "Spectroscopic Investigations in Connection with the Active Modification of Nitrogen. I.—Spectrum of the Afterglow," Prof. A. Fowler, F.R.S. and the Hon. R. J. Strutt, F.R.S.; "An Optical Method of Measuring Vapour Pressures; Vapour Pressure and Apparent Superheating of Solid Mercury," by Mr. C. Cuthbertson and Mrs. M. Cuthbertson; "The Hartley Tube Spectra of Mercury," by Dr. F. Horton; "The Production of Characteristic Röntgen Radiations," by Mr. R. Whiddington.

Royal Society of Arts.—The annual conversazione of this Society will be held at the Natural History Museum, Cromwell-road, S.W., on Tuesday next, May 30, from 9 to 12 midnight. Sir John Cameron Lamb, C.B. and the members of the Council will receive the guests.

Yorkshire Section of the Institution of Electrical Engineers.—At the annual general meeting of this section of the Institution of Electrical Engineers, which was held on May 17th, the following gentlemen were elected for the ensuing session: *Chairman*, Mr. T. Harding Vice-*Chairmen*, Messrs. Wilson Hartnell and W. Emmott; Mr. H. Dickinson; *New Members of the Committee*, Messrs. D. A. Parr, H. Visger, W. N. Y. King and E. S. Rayner. The meeting sympathetic reference was made by the chairman to the death of Sir Nathan Bodington, Vice-Chancellor of the Leeds University, and a vote of condolence was passed to Lady Bodington in her bereavement.

Victorian Institute of Electrical Engineers.—At the recent annual general meeting it was reported that the membership roll was 114, an increase of 48 over the previous year.

The Council for 1911 was elected. The President is Mr. P. Rosling; Messrs. J. H. D. Brearley and W. H. Alabaster being vice-presidents and Mr. E. H. W. Westwood. Secretary. It was reported further that strong endeavours had been made to bring about amalgamation with the New South Wales Electrical Association, and it was expected that something definite in the matter of the formation of the Victorian Institute of Electrical Engineers would be settled shortly. A discussion took place regarding the licensing of wiremen.

Mr. W. G. Murray desired that the municipal authorities be approached in the matter. The only way to obviate bad workmanship was to subject the wiremen in the same way as was done with engineers and plumbers. This would give the authorities control over the men. If a man wired a building in a faulty manner, then he should have his licence suspended for 6 or 12 months, and that would be the means of keeping a standard of work. A man should also be made responsible for the material used as well as for the work done.

Mr. P. Rosling stated that the committee had considered the matter, but nothing could be done without passing an Act of Parliament. He, therefore suggested that the matter should be left over until the wiremen's wages board was settled.

Mr. E. H. W. Westwood said that in Wellington (N.Z.) no wireman was allowed to touch the council's mains unless he held a licence, but he believed the whole thing had proved a failure.

It was decided to bring the matter before the Council.

The Tramways and Light Railways Association.—The "Journal" of this association for June contains copies of the Board of Trade Regulations regarding guard wires; the Home Office Report regarding street accidents caused by vehicles; details relating to the association's congress to be held at Edinburgh in July, and various other general matters relating to the association.

EDUCATIONAL NOTICE.

"The Application of Hyperbolic Functions to Electrical Engineering."—A series of lectures on this subject addressed to advanced students of the University of London and others interested will be delivered by Dr. A. E. Kennelly on May 29th and the four following days at the Institution of Electrical Engineers. The lectures will begin at 5:30 p.m. The ground to be covered is sufficiently indicated by the following syllabus. *Lecture I.*—Hyperbolic angles and their properties; the relations between circular and hyperbolic angles; applications of hyperbolic functions to continuous-current lines of uniform resistance and leakance. *Lecture II.*—The simple representation of artificial lines, and alternating-current lines by hyperbolic angles; equivalent lines (T and π). *Lecture III.*—The distribution of voltage and current over alternating-current power-transmission lines as simplified by the use of hyperbolic angles. *Lecture IV.*—The distribution of voltage and current over telephone lines, both simple and loaded: (1) by hyperbolic angles; (2) by equivalent circuits. *Lecture V.*—The hyperbolic theory of voltage and current on composite telephone lines and on long submarine telegraph cables; miscellaneous applications of hyperbolic functions in electrical engineering. Admission to these lectures is free by ticket to be obtained from the secretary of the Institution.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, May 26th (to-day).

PHYSICAL SOCIETY.

3 p.m. Visit to the National Physical Laboratory, Bushy House, Teddington.

INSTITUTION OF ELECTRICAL ENGINEERS.

4:30 p.m. Annual General Meeting at Victoria Embankment.

SATURDAY, May 27th.

ASSOCIATION OF ENGINEERS-IN-CHARGE.

9 a.m. Visit to the Works of the Cambridge Scientific Instrument Co., Cambridge.

MONDAY, May 29th.

UNIVERSITY OF LONDON.

5:30 p.m. First Lecture (at the Institution of Electrical Engineers) on "The Application of Hyperbolic Functions to Electrical Engineering," by Dr. A. E. Kennelly. *The remaining lectures of the course will be delivered on the four following evenings at the same time.*

THURSDAY, June 1st.

ROYAL INSTITUTION.

3 p.m. Meeting at Albemarle-street. Lecture on "Changes Effected by Light," by Mr. T. Thorne Baker.

FRIDAY, June 2nd.

ROYAL INSTITUTION.

9 p.m. Meeting at Albemarle-street. Discourse on "Radio-telegraphy," by Commendatore G. Marconi.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued for the current week:—

Monday, 29th, "A" Company.—Infantry Drill, 7 to 8 p.m. Technical Drill, 8 to 10 p.m.

Tuesday, 30th, "B" Company.—Technical Drill, 7:30 to 10 p.m.

Wednesday, 31st, All Companies.—Annual Course of Musketry at Purfleet Rifle Ranges. Tickets can be obtained at Headquarters on application.

Thursday, June 1st, "C" Company.—Recruits' Infantry Drill, 6:30 to 7:30 p.m. Technical Drill, 7 to 8:15 p.m. Company Drill at Millbank Barracks, 8:30 to 9 p.m. Dress, Drill order.

Friday, June 2nd, "D" Company.—Recruits' Infantry Drill, 7 to 8 p.m. Company Drill, at Millbank Barracks, 7:30 to 9 p.m. Technical Drill, 9 to 10 p.m.

Saturday, June 3.—No parades.

AUTOMATIC TELEPHONE EXCHANGE SYSTEMS.*

BY W. AITKEN.

(*Concluded from page 203.*)

Summary.—A description is first given of a switchboard designed by the author, in which the connection is made manually but disconnection is automatic. The full automatic telephone system of the Automatic Electric Co. is next described in detail. A comparison is finally made between the features of automatic and manual systems, and an estimate is made of the comparative cost of working.

We will recapitulate the operation of a 1,000-line equipment. On an exchange of this size there will be 1,000 line switches (*i.e.*, one per line), 100 first selectors and 100 connectors. It is found in practice that a 10 per cent. basis is ample for ordinary exchanges; very rarely are there more than 10 connections (or 20 telephones talking) per 100 lines. After the receiver has been lifted, and before the dial has been revolved to the stop, the line switch has done its work and connected with an idle selector. If the number desired is 865, the caller will place a finger over the number 8 and revolve the dial to the stop. The selector will step up to the eighth level of contacts and come to rest on the first set of contacts if these are disengaged; if, however, that line to a connector is already engaged, the shaft will continue to rotate automatically until an idle connector line is found. The finger will then be placed over the figure 6, and the dial revolved to the stop, when the connector will step up to the sixth level, but will not make contact with any line. The finger will then be placed over the figure 5, and the dial revolved to the stop, when the shaft will rotate until the fifth group of springs on the sixth level is reached. When stations below 100 in an exchange of 1,000 lines are called the number is preceded by O, so that the sequence of operations may remain the same, or the two figure numbers will be omitted. On 100,000-line systems, instead of using five figures to identify a line, four figures are used preceded by a letter, as being easier to remember, and generally the letters indicate different exchange, as the system is usually built up of 10 exchanges, or 10 groups of exchanges, each having a capacity of 10,000 lines.

It has been found in practice that 10 per cent. of lines between first and second selectors in very large installations is unnecessarily high, owing to the rapidity of service, and a "secondary line switch" has been introduced to reduce that number. Both line switches act automatically and are quite independent of any movement of the dial. This still further reduces the number of lines between exchanges. To equalise the traffic on the first selectors an intermediate distributing board is introduced between the primary and secondary line switches. By the introduction of secondary line switches any subscriber's line may use any first selector and any junction line is made available to any first selector.

The opinion is commonly held that the automatic system is most inflexible, but quite the contrary has proved the case in practice, and all special services, such as metering or registering calls, party line working, private branch exchange working, &c., are now standardised.

Party Line Working.—A four-party frequency system is used with the bells of the subscribers' instruments tuned to respond to frequencies of $16\frac{2}{3}$ cycles, $33\frac{1}{3}$ cycles, 50 cycles, $66\frac{2}{3}$ cycles. A group of party lines will be multipled over four connectors, and to each connector will be supplied ringing current of one frequency only, so that when a connector is brought into use only one particular subscriber on the line can be called.

Call Offices.—These are operated in a simple but very ingenious manner. The subscriber calls in the usual way, but when the called station answers the reversed current actuates an electromagnet in the coin box which short-circuits the microphone and places a shunt about the receiver, so that the caller can but faintly hear the party called. On the insertion of the requisite coin the talking is made normal.

Sub-District Stations.—A great feature of the automatic system is that it is not essential to concentrate a great number of lines in any one building. The system will work as efficiently if 10,000 lines are in one building as in 10 exchanges of 1,000 lines each. The apparatus, with the exception of, probably, the power plant, will be exactly similar, but the street cable plant will be very different. Instead of 10,000 lines converging to one centre, there will be, in addition to the shorter converging lines, the 10 per cent. of lines between first and second selectors between exchanges. It will thus be seen how efficiently the automatic system meets the varied needs of a great city, where a residential district of a few years ago with few telephones becomes a busy business centre requiring many telephones.

In existing manual systems automatic district stations may be used with advantage as valuable adjuncts, either to avoid expensive underground cable work, the provision of new manual plant, or expensive additions to existing plant of limited capacity. The instruments on such an automatic equipment would be of any of the well-known patterns without any automatic feature whatever. At the district station they would be connected to line switches for outgoing work. At the manual exchanges these junction lines would end on the usual line and cut-off relay, answering jack, and calling lamp, or on single cord equipment like manual incoming junctions. On the removal of the receiver to call, the line switch would connect with a disengaged junction instantly, and the line lamp would glow, and the operator would complete the connection in the usual way, the service being absolutely similar to a connection in a purely manual exchange. Fig. 3 shows such an arrangement. For outgoing calls from the manual exchange, an operator would have, in addition to the ordinary double cord equipment, a switch to connect up a dial-calling device by which, after making the connection, she would call the number required in a manner similar to a subscriber calling on a full automatic system. All the lines in the district station are multipled on to connector banks to allow of them being called. Another method is to multiple the outgoing junctions over the manual board and on to a controlling operator's position which may be away from

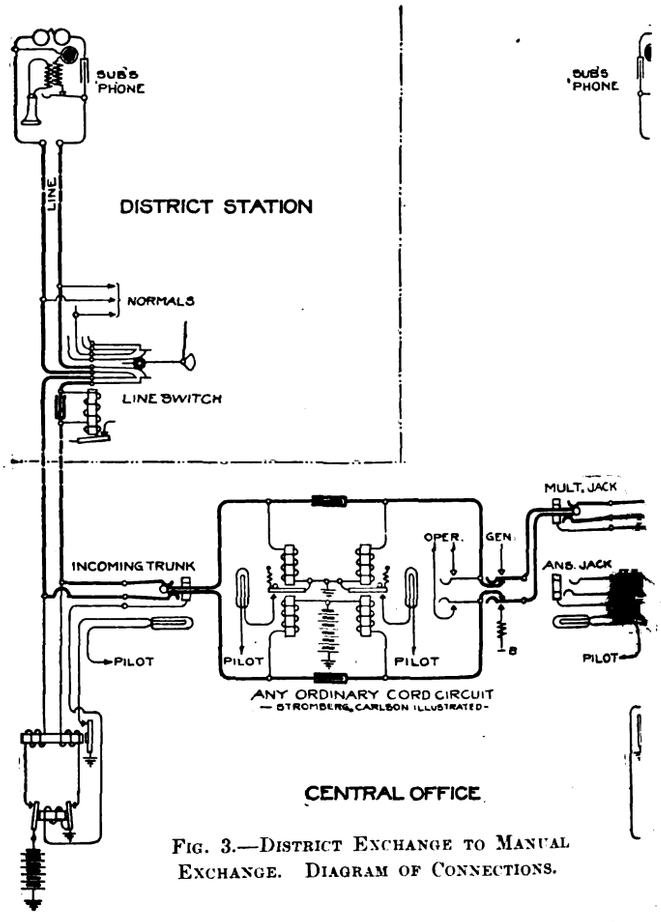

FIG. 3.—DISTRICT EXCHANGE TO MANUAL EXCHANGE. DIAGRAM OF CONNECTIONS.

the multiple. This operator would have a key in each junction switch in the dial-calling device and a lamp to indicate what lir were engaged.

Such an important and far-reaching subject as a change from manual to an automatic system must be considered very seriou from various points of view. In some countries objection has be raised to the automatic system because it will do away with one fo of employment which is very suitable for women; in new countr where women are scarce the automatic appeals as a way out of great difficulty. Considering the question, however, quite ap from sentiment, it will be interesting to investigate it, briefly a generally, from the points of view of efficiency, capital cost, a maintenance.

Efficiency.—The manual system is now as near perfection from operating point of view as it can be brought, and increased efficier can only be obtained by refinements due to more expert operat and thorough supervision. The principle of working is that the su scriber should only remove the receiver, state his requirements, a replace the receiver on the switch-hook, all operating beyond be performed by experts. This sounds good and simple, but it depen firstly, on the articulation of the speaker, who may be from a county or any country, and, secondly, on the ear and understand

* Abstract of a Paper read before the Institution of Electrical Engineers.

Digitized by Google

of the operator to interpret the words before giving effect to them. Again, in a city like London, something like 75 per cent. of the calls are over junction lines, which means that the first operator has to repeat the number required to a second operator. In the automatic system the responsibility for getting any number, no matter how large, is entirely on the caller. If a blunder is made, the caller has only himself to blame. For rapidity of service the automatic has the advantage unquestionably, and the secrecy of the conversations will also appeal to many.

Capital Cost.—This, for the actual exchange equipment in small exchanges, is much more with automatic than with manual, but as the increase in size they approach nearer until at about 10,000 lines they are equal in cost. This is for single exchange equipment, but when the telephoning of a great city is considered the results may be very different. The subject is, however, very complex and would require very careful study of a particular area to determine exact cost. This may be noted, however, that whereas the manual system increases with an ever-increasing ratio owing to the increase of junction lines with their complicated circuits, huge multiples, and attendant operators, the cost of the automatic system increases much more gradually. The apparatus increases on the per centage basis, and the junction lines are actually fewer, as they carry a greater number of subscribers' calls owing to the rapidity of the service.

The figures obtainable re cost are very few and are based entirely on American practice. The cost of installing, both manual and automatic equipments, will be greater, I think, in this country than in America. The following schedule of comparative costs for manual and automatic exchanges of 5,000 and 10,000 lines is taken from a paper by Mr. Lee Campbell. The cost per line of the manual exchanges given is low if ancilliary lamps are used. The increased cost of automatic equipment is more than counterbalanced by the reduction in cost of building, the cubic space necessary being only half that required for a manual equipment.

The manual system is seen at its worst when sub-division takes place. Owing to the cost of line equipment it is not economical practice to concentrate all lines on one large central exchange, even were this could cope with the requirements of a town. It is usually advisable, therefore, to have district exchanges, and the schedule shows the results when 10,000 lines are divided between two 4,000-line and two 1,000-line exchanges. Owing to junction work the A operators' load is reduced from say, 240 calls per busy hour to 115. B operators have to be introduced for work between exchanges, and the total operators will be increased from about 99 to 140. The cost of buildings will also be much greater. The automatic equipment will not be increased seriously, the cost for power plant will be greater, the cost of buildings will not be so serious as with the manual. For while the automatic the efficiency will remain the same as if concentrated in one building, whilst in the manual the service will be considerably slower, and the liability to wrong connection much greater owing to the repetition of numbers, &c.

It is a very difficult matter to deal with the saving effected in conductor cable for lines, unless a particular town be laid out for each case; but, generally, I think, it must be conceded that as the efficiency remains always at 100 per cent. efficiency, no matter how the lines are distributed, there must be a great saving owing to the possible reduction of the average length of the subscribers' lines, the greater number of junction lines owing to their greater carrying capacity under automatic conditions, and to the greater flexibility and the feasibility of opening an automatic exchange owing to the greater telephonic density of a district, whereas a manual exchange could not be opened at the cost of reducing the efficiency and increasing the operating cost of the whole area. The cost of buildings works out much less on an automatic system as the equipment is much less in compact—no kitchen, rest-room, and other conveniences for operators are necessary. The furnishings, decorations, electric light and fittings are much simpler.

Maintenance.—All operators' expenses are saved except such as are required for trunk service, information desks, and the like. Against this, of course, has to be placed the cost of electricians or mechanics. One good man is usually provided for every 1,000 lines.

The Automatic Electric Co. have lately published a certificate over the signature of the President of the Citizens Telephone Co., Grand Rapids, that the cost of replacing parts, due to defective workmanship, or material, or ordinary wear and tear, during seven years, amounted to $962·62, an average of $137·52 per annum, or 0·9d. per line per annum, for the average of 7,500 lines in service. This sum included all central equipment, except power plant, and also the dial switches in the telephones.

Similar data for manual equipments is not readily available. From figures obtained in connection with the Chicago manual system the average cost of repairs on central equipments and instruments is about 27s. per line per annum, the cost of repairs on exchange equipment alone averaging about 17s. For Seattle the figures are given as 10s. per line per annum line and exchange equipment, and 10s. per subscriber's instrument. It would be interesting to hear what the costs of repairs are in this country, and further figures regarding automatic equipments.

Semi-automatic systems have been suggested as meeting the requirements of future development, but it is very doubtful if they can be made an economical success, and they seem to me to be good only as a transition measure. The "Traffic Distributor" system of the Automatic Electric Co. meets the requirements in an efficient manner. In this the multiple of a manual exchange is retained, but the answering jacks, calling lamps, line and cut-off relays, and intermediate distributing frame are omitted. The keyboard equipment is simplified in that, instead of double cords, only as many single cords are provided as the operator can attend to. From the main frame, lines in parallel to the multiple are carried to Keith primary line switches, with their 10 per cent. of lines to secondary line switches, so that the number of lines is reduced until they are just sufficient to carry the traffic. These lines are then distributed among as many operators as are necessary to cope efficiently with the work, the lines ending on the single cords already mentioned. Switching devices are introduced so that position after position may be thrown out of use, and the work therefore concentrated so that it can be dealt with in the most economical and efficient manner. It is to be noted particularly that the calls are distributed in rotation to the different operators, so that all have an equal amount of work to perform.

The instruments at the sub-stations are exactly the manual common battery instrument, and the subscriber calls by lifting the receiver. Immediately the line switches act one after the other and extend the line to the plug and the lamp associated with the plug glows. (Meantime the master switch has moved all lines of a group to the next spare circuit to the next operator so that the line is pre-selected.) The operator pulls over the speaking key to answer, lifts the plug, tests and completes the connection in the usual manner.

Time does not permit of the subject of automatic telephony being dealt with exhaustively. The Lorimer, the American Automatic Co.'s and other systems would require another Paper to deal adequately with them. That there is a great future before automatic telephony I am convinced, and my Paper can only be looked on as preparing the way for more detailed consideration of the subject.

We give below an abstract of the discussion on Mr. Aitken's Paper which took place last week at the Institution of Electrical Engineers.

Mr. J. E. KINGSBURY suggested with regard to nomenclature that what was now termed automatic switching should be called machine switching and what was called full automatic should be described as machine calling and machine switching. That would differentiate three different systems: Full automatic, semi-automatic, and so-called full manual. Mr. Aitken was a "whole-hogger" for the full automatic, and did not believe anything else could be other than transitory. He (Mr. Kingsbury) did not say he was wrong, but the installation or modification of a telephone system was a work of considerable cost and extreme gravity; and it was a complex engineering problem mixed up with a complex

social problem. Mr. Carty, who read a Paper on this subject a short time ago, indicated that telephone engineers must be careful that they might not be led away by the enthusiasm of the inventor or manufacturer. Mr. Aitken had turned the tables on the telephone engineer, and he (Mr. Kingsbury), as a manufacturer, said it was only enthusiasts who thought the public were incapable of operating a telephone calling machine. Mr. Aitken said the telephone, in transmitting the intelligence to the operator, might be indistinct; so might the telephonic conversation, and if a telephone could be made to transmit a conversation it ought to be able to transmit the number the subscriber required. Would the subscriber always be sure of sending the right number by machinery? He did not wish to depreciate the subscriber, but there was a difference between sending a machine call on the telephone and operating an automatic machine for a pennyworth of chocolate. He had condemned proposals made for placing upon the subscriber the responsibility of any errors in switching, and he again entered his objection on the same grounds. Those responsible should take care the service was a sound and perfect one, and not seek to evade any responsibility.

Mr. F. Gill said he must disclaim credit for the suggestion Mr. Aitken attributed to him in the Paper. Something he had said must have been inverted, because the National Telephone Co. thought the intervention of the private exchange operator was very important; he hardly thought she could be got rid of by automatic gear, no matter how it was worked. Calls coming in had to be filtered and the correct representative found, while calls going out had to be nursed through, and the expensive time of the principal saved by the less expensive time of the operator. It was better to give the supervisory signal to the private branch exchange than to the central. Some subscribers did not furnish good attention at their private branch exchanges, but that did not make any difference to the principle. Opposite page 26 of the Paper there was a diagram of a 100,000-line system. All down the 10,000-line exchange the junction lines between primary and secondary line switches were on a 10 per cent. basis, but each 1,000 subscribers might have different calling rates, and therefore he should say the number of subscribers' lines for each 100 such junction lines need not necessarily be 1,000. In other parts of the Paper the author referred to 10 per cent. of the junction lines; he (Mr. Gill) assumed that was only illustrative, and that the junction lines would be proportioned to the traffic. On page 28 of the Paper there was a mention of 22½ calls per junction per busy hour; but it would be unsafe for anybody to translate those figures into this country until it could be shown that they applied. They did not apply in London, where the duration of the actual conversation was very much longer than was indicated by those figures. There was also a reference to all special services being given by the automatic system. All special services was rather a large order. In the National system there were 60 different instructions which might require to be given to the operator as to the way different services should be handled, and there must be different rates to meet the different conditions and requirements of the public. Last time he (Mr. Gill) was in the States he came across the old figure (which Mr. Aitken gave) of one man per 1,000 lines for maintenance. He thought he had run that one man to earth, for he found he worked eight hours per day, and that there were really on the pay roll three men per 1,000 lines working eight hours per day each. No advocate of the manual systems objected to using automatic gear; the question was where should it be used. Mr. Aitken truly said the proper thing to do was to study an area. The manual system was better here and the automatic system was better there. The only way to set to work was to take a large area and study it right out to the bottom in all its bearings, having first determined the kind of service to be given, and then, he thought, a conclusion might be arrived at. In the table of costs on page 37 Mr. Aitken did not indicate the traffic figures on which the costs were based. The costs would be largely dependent on the calling rates, &c. The Paper by Mr. Carty was well worth reading by anybody interested in the subject. He took an area, studied it, and gave his results, and his results put a serious onus on anyone wishing to prove either that the automatic was or was not the proper system to use.

Mr. A. Whalley said there was evidence in Mr. Aitken's Paper that the subject of automatic telephony could not be pooh-poohed, and that it was time for the business man to be consulted. If there were 300,000 telephones working on this system there must be something in it. It was claimed by the advocates or manufacturers of the automatic system that the disconnection of the exchange lines was instantaneous. The bulk of conversations in London were carried on through several exchanges with manual operators, each of whom must observe the clearing signal and be free to attend to it. Each of the manual operators was provided, as a rule, with 17 pairs of cords, and had to attend to between 100 and 200 subscribers who were sending calls in, and at the same time to receive signals from those already connected demanding instant disconnection. The result was there was a longer wait than there ought to be for exchange lines to be disconnected. All users of the telephone in London knew that the service was far from being as quick as it was with identically the same apparatus in New York. If there were any serious intention of quickening up and improving the service and saving the time of the business community by adopting the latest system, an effort should be made to investigate by sending someone to stay in the States and compare the automatic systems with the manual practice, and even if the cost were double, it would be worth while having a 10,000 to 50,000 line exchange put down on trial if there was going to be any saving of time to the business man.

Mr. M. S. Conner said it would be wise to analyse of what the automatic system consisted. It would appear that it consisted of doing a certain number of things automatically, and a certain number by machines under the control of the subscriber. He believed all it did really automatically, with the exception of the instantaneous disconnection, was found in the manual equipment. The automatic registering of calls, the ringing of party lines and the connecting of each subscriber with a different jack were well known in the manual system. He believed the apparatus for reducing the junction lines between exchanges was more the result of the decimal system of junctions than of the automatic system. All that had to be compared in the two systems was the making of connections by machines and by operators. After making investigations, he felt that the automatic system, so called, was a successful one; the subscribers liked it, the service was quick, and he thought they were reduced to considering the question from a financial point of view. The expense of operators was rarely one-fourth of the total expenses, and under good management should only be one-fifth, even if the system reached 30,000 or 40,000 subscribers. This figure was made up in cost of maintenance and depreciation in the automatic systems. One could hardly read the five pages of the Paper describing the putting through of a connection by the automatic system without realising the enormous number of parts and the enormous number of contacts that had to be made before the connection was established, and if the cost of a piece of mechanism could be judged by the number of parts, the automatic must cost more than the manual system. They should not compare the oldest form of telephone used on the manual system with the latest form used on the automatic system. The maintenance of the subscribers' instrument in the former case might be anything from $1 to $10 (4s. to £2); but in the latter it appeared to be less than 2 c. (1d.) all the way through. About four years ago he made a visit to the automatic exchange at Columbus, Ohio. It was in the afternoon, and four or five "trouble clerks" were taking down complaints as fast as they could answer the calls. At an ordinary exchange at St. Louis, that had more subscribers than the Columbus exchange, there was only one employ at the trouble clerks' desk at 11 o'clock in the morning, the busiest time of the day; and he was reading the morning paper. In regard to Mr Aitken's figures as to cost of buildings, operators were employed in automatic exchanges, and therefore accommodation must be made for them and there was no reason for having more elaborate premises if there were more of them. Audited balance-sheets of automatic exchanges did not show greater earning power than manual systems. Some of the balance sheets showed rather small expenses, but there were larger additions to capital, and the capital value of the stations increased each year, which was not a healthy sign. It was evident to him that, up to the present no automatic system gave a quite reliable service at the same expense as the corresponding service could be given by modern manual equipment. Mr. Aitken stated in the Table in his Paper that a manual switchboard had a life of 10 years, but there were a large number that had been in operation more than 15 years, and he believed the Postmaster-General was expected shortly to acquire a large number of exchanges that had been in operation more than 10 years. By means of recent improvements in the choice of materials the life of articles which rapidly wore out, such as springs, jacks and plugs, had been greatly prolonged, and a multiple switchboard could now be got that would be in good operating condition after 25 years, apart from the replacement of plugs and cords. The automatic systems installed from 14 to 15 years ago had passed away a long time since. Switching mechanism, consisting of the vertical and rotary motions of the vertical shaft of the selector and connector did not go through a cycle of operations. The first step of both of these motions was easy, the second was not always easy, and the first step must get a great many times more wear than the last. When this step was enough to throw the wipers out of adjustment the switch jumped, and the vertical shaft must be replaced in a short time. There might be hope for automatic telephony if, by some improvement or invention, a large proportion of the number of parts required to make up the mechanism could be done away with. If that were done, what remained could be made in a more robust and scientific manner and otherwise made equal to the quality of the apparatus used on manual equipments. When it was remembered that the Strowger patents were taken out in 1888, and that during 23 years enormous sums of money had been expended in bringing this device to perfection, one got rather discouraged as to any advantageous outcome. The semi-automatic system appeared to have the disadvantages of both systems and the advantages of neither.

Mr. R. Scruby said much might have been done in automatic telephony in England, as there was not the same opposition to withstand as there had been in the United States. He was sure the automatic was the best system in the end, although he did not forget the high efficiency of the manual services of the Allmanna exchange in Stockholm and the China Town exchange (worked by Chinamen) in San Francisco. He had an automatic instrument in the house he lived in at Dayton, Ohio, and never got a wrong connection. A cosmopolitan telephone was a necessity. He had great difficulty in Stockholm in getting people on the telephone, owing to his atrocious Swedish, and if the automatic system had been installed he would have used the telephone oftener, as everybody he wanted to speak to could speak English. He trusted Mr Aitken's Paper would be a means of starting the automatic telephone service in England.

Mr. T. Holme, in a written communication, thought the author had made out a case for the automatic system for large inter-office schemes, as the elimination of B as well as A operators, and the economies in junctions would materially affect the rental to be charged for the service. The costs on page 37 of the Paper needed revision from the British point of view. They had a 10-line automatic exchange in connection with the service at Hull in a village about 6 miles from the central exchange. It consisted of the usual rotary and release mechanism, with a busy back circuit which was only set up when an engaged line was tried. The subscribers' instruments were fitted with hand generators, and they rang through at

Digitized by Google

getting up a number. The capital cost was £4 per subscriber for the exchange apparatus and £2. 10s. for the instruments. The system had been working just a year, and the maintenance cost for that time was extremely low.

Mr. A. L. STANTON, in a written communication, said the perusal of the Paper showed that the cost of installing single exchange equipments under 10,000 lines was much less with the manual than with the automatic system. In this country most exchanges came within that category. Further, his experience was that complex questions involved by efficient intercommunication and distribution did not, at least in provincial areas, admit of consideration along American lines. Staffs on automatic systems must be trained to cope with duties demanding a higher order of average ability than was now to be found available on manual service. It would be of interest to know what information was available regarding the reliability of adjustments, what effects resulted from variation in voltage, and what was the minimum insulation value for distribution permissible. It was very evident the problems to be faced when considering this country as a field of probable development for full automatic equipment were such as would demand very serious attention from a financial point of view. He was of opinion that at no distant date conditions would arise containing the groundwork of full automatic possibilities. Small areas would appear to be suitable localities for testing this equipment.

Mr. D. H. KENNEDY submitted that the system described by Mr. Aitken was better described by using two words than one—it was the automatic switching system. The manual switching system had been referred to as the non-automatic signalling system (that meant the magneto system) and the automatic signalling system (which referred to the central battery system).

Mr. W. AITKEN, in reply, said he had no idea of doing away with the operators in branch exchanges. Although the Automatic Electric Co. recommended full automatic for the main exchanges, in their private branch exchanges, to meet local conditions that existed in warehouses and works where it was not always convenient to put a connection through they always had a manual operator, and that was why it appeared from the statistics there were so many operators required for automatic systems—they were using branch exchanges. The automatic disconnecting board (shown on the table) was primarily meant for offices where there was no regular attendant. Mr. Conner seemed to be discouraged with the progress made with automatic systems. He (Mr. Aitken) thought there was every reason for encouragement from the progress made as regarded development and manufacture of late years. In America the system was progressing, and an independent company had gone into competition with the manual system in Chicago. Mr. Conner acknowledged that the blocks and cords in the manual exchanges were a very serious item of cost. There was no doubt about that, but from all the statistics he (Mr. Aitken) had been able to get hold of there appeared to be comparatively few wearing parts in the automatic system. The wipers were practically the only parts that had to be renewed fairly frequently. The vertical shafts had to be renewed at times, but he had not heard of them as being a serious cause of expense. He did not think the 2 c. (1d.) per annum really was the full cost of the maintenance of the system, but he gave it for what it was worth. It was supplied by the president of an operating company, who would naturally be expected to make the best possible bargain with the Automatic Co.

NOTE ON CROVA'S METHOD OF HETEROCHROMATIC PHOTOMETRY.*

BY H. E. IVES.

Summary.—The author's investigation shows that the oft-repeated statement that the equivalent wave-length is the wave-length of maximum sensibility is in error, and that any equivalent wave-length is such to a given degree of accuracy for but a limited range of black body temperatures.

Crova suggested as a method of comparing the intensities of different coloured lights a comparison of their intensities at a single wave-length. By this means the actual photometry is reduced to the photometry of lights of the same colour. For its utility and accuracy this method depends on the validity of a certain assumption—namely, that there can be found a wave-length at which the relative energy emission in different illuminants is proportional to their total light. Such a wave-length may be looked for near the brightest part of the spectrum, since, owing to the very pronounced maximum of visual sensibility near 0·545μ and its rapid drop in value on either side, this point of maximum brightness is not greatly different for all the common incandescent illuminants. Obviously the method can only be applicable to light sources possessing continuous spectra, such as the black body, and sources whose energy distribution is not greatly different from the black body.

Crova found experimentally that he could measure the relative illumination from sunlight and from a Carcel lamp by a determination of the relative intensity at wave-length 0·582μ. It has been commonly assumed that this wave-length would also serve for the comparison of any illuminants lying between these two in colour, either with one of these or with each other. Applications of the original idea of Crova have also been made by Lord Rayleigh and other scientists.

While this method of heterochromatic photometry has not been very widely used, partly because of its limitation to continuous spectra and partly because of practical difficulties, it is nevertheless of considerable experimental and theoretic interest. In connection with a problem on the efficiency of incandescent solid radiation, in which incandescent lamps are to be employed, the writer has found it convenient to make use of Crova's method. It seemed advisable before so doing to investigate the range within which the method

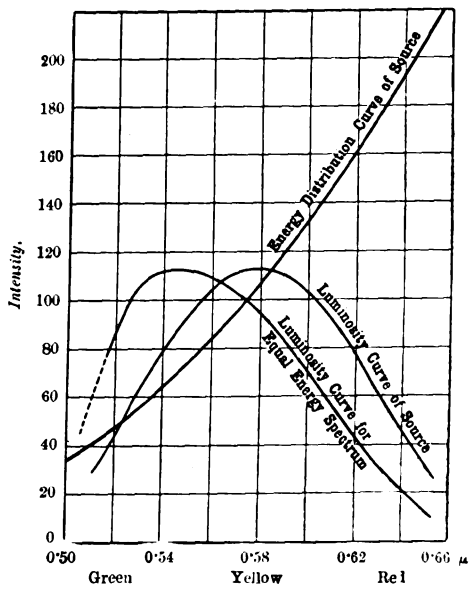

FIG. 1.

would be valid; and from this investigation it appears that certain of the assumptions commonly made in its use are not entirely correct—namely, (1) that the equivalent wave-length is that corresponding to the maximum of visual sensibility, and (2) to use the equivalent wave-length idea over a large range of illuminant colours (such as black body temperatures) without raising any question as to the limits within which the method holds.

The error in the first assumption, taking a tungsten lamp, is most clearly indicated diagrammatically in Fig. 1. Here is given the actual luminosity curve of a source (tungsten lamp through prism, &c.) and the luminosity curve for a spectrum of equal energy at all wave-lengths. The latter is the product of the luminosity values for the source by the reciprocals of the energy values. The curves

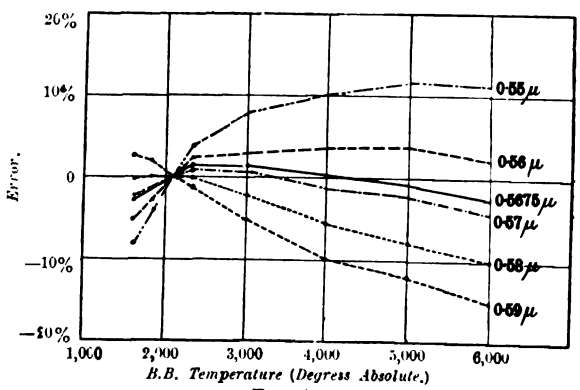

FIG. 2.

are drawn to be approximately of the same area, and, on the assumption that these areas are proportional to total light, it is at once evident that the wave-length of maximum sensibility, 0·545μ, does not give the relative light values, the error being about 20 per cent. The relative areas of the curves are actually given by the energy values at about wave-length 0·565μ. In other words, the equivalent wave-length lies somewhere between the maxima of luminosity of the sources under comparison, and the wave-length of maximum sensibility does not enter in.

With regard to the second assumption, Fig. 2 gives in graphical form some calculations on its validity in the case of the black body.

* Abstract of an article in "The Physical Review."

Digitized by Google

The method of obtaining these data is as follows: Black body energy emission curves were calculated from the Wien equation; these were then each multiplied by the luminosity values corresponding to the spectral wave-lengths. These values were taken from a recently determined normal luminosity curve, from observations by five observers at a moderately high illumination. The areas of the resultant curves (the type of which is exhibited in Fig. 1) are taken as proportional to the total light, as measured on a photometer.

Having in this manner determined the relative light values, the relative values for the energy at various wave-lengths were read off the energy distribution curves. A table was then made out, taking the light and energy values at 2,100 deg. abs. arbitrarily as the unit, and the changes in total light with temperature were compared with the changes in the emission at various wave-lengths in the spectrum. Fig. 2 gives the errors introduced by limiting the photometry to light of one wave-length, where the standard of intensity is the black body at 2,100 deg. When the measured light is the same in colour as the standard, any wave-length may be employed, hence the error at this point is zero.

Several facts are here brought out. First, no one wave-length can be used as an equivalent wave-length for more than a certain definite range of temperature for any given allowable error. The horizontal portion of each curve shows the temperature range through which the corresponding wave-length may be used as an equivalent to total light. In the second place it appears that the wave-length of maximum visual sensibility—in this case 0·545μ—is not the equivalent one for any black body comparisons except between 5,000 deg. and 6,000 deg.; that is, far above the temperatures represented by any incandescent lamp, or other artificial illuminant of the incandescent solid type.

Wave-length 0·5675μ has been picked out by trial as the one which could be employed for an equivalent wave-length over the longest range with the least error. The error with this wave-length is less than 3 per cent. in either direction. If, however, the method is to be used only within the limits of temperature represented by the ordinary incandescent lamps—namely, 1,600 deg. to 2,400 deg. abs.—wave-length 0·58μ should be chosen. These results were very satisfactorily confirmed by measurements on a tantalum lamp over a wide range of voltages.

HYDRO-ELECTRIC PLANTS IN NORWAY AND THEIR APPLICATION TO ELECTROCHEMICAL INDUSTRIES.*

BY A. SCOTT-HANSEN.

Summary.—The author details the electrical development which is likely to take place in the employment of the water power of Norway owing to electrochemical progress. He also describes a number of hydro-electric stations which are at present working or being erected.

On looking at the map of Norway it will be perceived an overwhelmingly large proportion of the country—in fact, 97 per cent.—consists of mountains and moorlands, lakes and marshes. Of this, the forests cover one-fourth, while the bulk is represented by mountain pastures, moorlands and sterile wastes at an altitude of 2,500 ft. or more above the sea. A large portion of the high mountainous land concentrates itself towards the west coast. Considerable mountain ranges rise from the elevated plateaux, the highest peak being Galhöpiggen, about 8,200 ft. above the sea, and in consequence of the meteorological conditions the west coast has a vastly greater rainfall than the interior or eastern parts of the country. In the Diocese of Bergen the rainfall has in places been recorded up to over 158 in. a year, especially in the vicinity of the glaciers Folgefond and Jostedalsbræ. A very few miles behind the chain of coast mountains the rainfall is very considerably diminished, and on the line of the watershed may be reckoned at under 40 in. On the eastern side, the rainfall diminishes gradually to 15·8 in. and even less.

Owing to the intermittent character of the supply due to snow, it is of primary importance to be able to store as much as possible of the supplies which, during the melting of the snows, would escape to sea. The nature of the country is peculiarly adapted for such storage, being indented with lakes of various size, which, owing to the depth and narrowness of the valleys, have frequently very contracted outlets. It is, therefore, easy to convert such lakes, at comparatively little outlay, into most valuable reservoirs, in which to store in summer the water arising from the winter snows, and, by letting out these stored supplies as required to supplement the natural flow and to maintain the regular amount needed for the production of constant power. To give an idea of the greatness of the possibilities in this direction, it may be mentioned that in one watershed—the eastern watershed of Skien from Mösvand to Hiterdalsvand—where the natural water-power was originally equal to about 50,000 H.P. the available horse-power can be raised to about 375,000.

The total water-power in Norway has been estimated at from five to seven million horse-power, but this is probably too low an estimate, as, although all the larger watercourses which are at all well known are included, there are undoubtedly numerous smaller and little-known falls that have not been reckoned, but which, when the time comes, can and will be made use of. Moreover, large portions of Northern Norway are practically unknown as regards their hydrography.

As regards facilities for storing up the water supply in reservoirs formed by damming the mountain lakes and rivers, in almost every instance firm rock foundations will be met with on which to build dams or in which to make channels, tunnels, or on which to lay pipes or conduits, flumes and so forth. The cost is, therefore, comparatively small, and though it will be dependent on various circumstances, it may be taken that the stations can supply power at prices of from about 22s. to 44s. per horse-power year at the power station—prices which enable the waterfalls to be taken into the service of the great industries.

The industries that are able to make use of the large powers, for instance, 50,000 H.P. to 100,000 H.P. for a single waterfall, are, not those which require power to actuate machinery, but must be of electrochemical or electrometallurgical nature. In the course of the present year the oxidation of the nitrogen of the atmosphere will make use of 170,000 H.P. to 180,000 H.P., and will, it is hoped, in the course of a few years employ further about 300,000 H.P. In the manufacture of calcium carbide about 60,000 H.P. are employed, and in other electrochemical and electrometallurgical industries about 20,000 H.P.; all the result of developments within the last 10 or 15 years.

FIG. 1.—A TIMBER "SNAG" AT THE VAMMA DAM.

Some characteristic examples of the constructional works executed at some of the largest waterfalls were illustrated by means of slides and showed the difficulties that were encountered and had to be overcome.

Glommen, the largest river in Norway, forms at its lower end a series of falls, aggregating about 300 ft., in a length of about 35 miles. This river has a discharge of up to 220 tons per sec, even in winter, since the latest regulation of the lake Mjösen. The fall can yield about 40,000 H.P. The water is led from above the fall through a channel blasted in the rock. In the power station there are at present installed five sets of electric generating machinery supplying three-phase alternating current at a frequency of 50. About 10,000 kw. of the power generated is transmitted by a line, 31 miles in length, to Christiania and the neighbourhood, and the remainder to the town of Sarpsborg, at a voltage of 60,000 volts in each case. Owing to the great difference between the level when the river is high or low, the power units are constructed with vertical shafts.

Another fall fully developed is that at the town of Sarpsborg, the last fall on the Glommen. Here are two power stations—Hafslund on the eastern, Borregaard on the western side of the river. Hafslund station is constructed for 24,000 H.P., which is chiefly supplied to electrochemical factories, amongst them a calcium carbide factory and zinc-smelting and refining works. This station also furnishes power to the thickly populated district round the town of Fredrikstad. At Hafslund the power units are also constructed with vertical shafts.

Borregaard is developed for a total of 26,000 H.P., which is exclusively used by the large works belonging to the proprietors—the

Kellner Partington Paper Pulp Co.—who chiefly manufacture wood-pulp and cellulose, but also have a carbide factory and a manufactory for ferro-silicum. These works are the largest in Norway, and employ between 2,000 and 3,000 hands.

Vamma, the third of these power stations on the lower part of Glommen River, is situated midway between the two previously mentioned, and is now in course of erection. The river at this point is about 220 yds. in width, and the dam has to be built in at least two sections. One-half of the river is shut off by a coffer dam of wood, made as impervious to water as possible. The space thus laid dry is cleared and blasted till a foundation is obtained in the solid rock, whereupon the lower part of the dam is built up in concrete, leaving openings in which large pipes are fixed in order to take the water when the river is low. This work can only be done in winter, when the river falls to between 100 and 200 tons per sec. As in this case enormous quantities of concrete are necessary, it was not possible the first winter to do more than to construct the foundation of the dam. In April the first flood may be looked for, and everything must be removed or it will be swept away. As spring advances the water rises rapidly, and in the course of a month increases to about 3,000 tons per sec., which flows with tremendous force over the foundations of the dam, and then the timber-floating begins.

A passage over the dam, when it is finished, has to be provided for the timber, and it is not easy to foresee what the timber may do. For instance, at Vamma it has been found that the timber can pile itself up in immense quantities in front of the dam and also at the sides, by which considerable damage may be done and a number of logs be smashed. If such a "snag" cannot be quickly cleared, there is possibility of the masses damming up the whole river and incal-

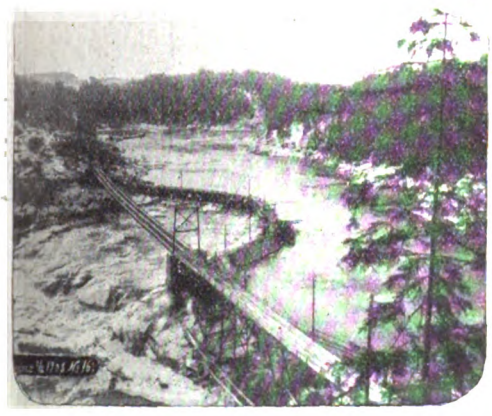

Fig. 2.—The Dam, Vamma.

culable damage being done. During the autumn the water diminishes, and in November or December work may be resumed on the dam. The discharge having gone down to about 400 tons per second, it is carried off through the openings in the foundations, while the other half is shut off by a coffer dam. This work is now almost completed. A typical "snag" on the Vamma Dam is shown in Fig. 1.

The dam at Vamma (Fig. 2) is to be about 90 ft. high, and the power station will be in the centre of the river-bed immediately below the dam. There will be 10 or 12 units or sets of machinery, each of about 7,000 H.P. The power will be partly used for supplying light and motive power, and partly for a factory for nitrogenous products. This Vamma dam will be one of the largest in Europe, and is specially interesting as being constructed in a rapid river discharging a very considerable amount of water.

There are a number of minor water-power stations in the south of Norway, mostly supplying the towns, including those of Christiania, Drammen, Larvik, Skien, Krageröe, Christianssand, Gjössing-fjord, Vadheim and Trodjeim.

At Telemarken there is first the Svælgfoss station (Fig. 3) with a capacity of 40,000 H.P., which supplies the well-known factory for nitrogenous products at Notodden. This power station is of a different type from those described on the Glommen, as the river flows here with a rapid fall between perpendicular cliffs, and the power station is constructed for a fall of about 165 ft., with a flow of 75 tons per second.

At the head of the fall, where the river is constructed in a ravine of only a few yards width, a dam has been built raising the original level of the water about 45 ft. A tunnel of about 500 sq. ft. in section leads the water to a reservoir, from which it is conveyed by four flumes through the solid rock direct to the turbines in the power station. The latter is placed in the river bed, up against the wall of the cliff, so that it looks almost like a swallow's nest built against the wall.

In the power station are four sets of machinery, each of 10,000 H.P. capacity, and which are, indeed, capable of developing over 13,000 H.P. each. The power is transmitted to Notodden by a cable 4 km. in length at a voltage of 10,000 volts. The current is three-phase alternating at a frequency of 50.

By regulating the height and outflow of some large lakes on the high mountains, it is believed that the amount of water discharged by the river will be brought up to about 90 tons per second, and in order to utilise this the Norsk Hydro-Electric Nitrogen Co. have just commenced the construction of another power station to which the water will be conveyed by two long flumes from the same reservoir. The power station will be placed some 100 metres further down the river, and will be fitted with two sets of machinery each of 10,000 H.P., of which one will serve as a reserve for both stations.

Notodden saltpetre works will, in the course of the present year, obtain a considerable addition to their available power from a station which is being installed about ¾ mile down the river, at Lienfoss. A dam about 55 ft. high has been built here right across the river, and immediately below it the power station has been constructed for 15,000 H.P. and a reserve of 5,000, there being four sets of 5,000 each. The machines work here, as at Svælgfoss, at a primary tension of 10,000 volts.

In order to utilise the power obtainable from the Reeking waterfall, the Rjukan Co. have constructed a railway from Notodden to the south end of Lake Tinsjö, a distance of 20 miles. The Norsk Hydro-Electric Co. have built a dam at the outlet of the lake. This dam is of concrete of unusually wide and deep foundations, as no

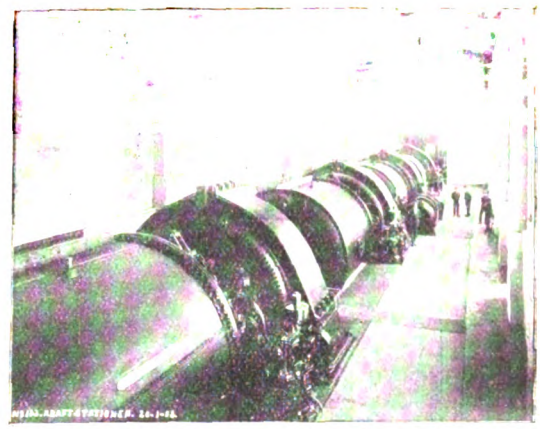

Fig. 3.—Interior of Svælgfoss Power Station.

solid rock was reached, the natural barrier consisting entirely of stones and gravel and sand. This dam for regulating the flow from the lake raises the level 4 metres, and thus provides a reservoir of 250 tons of water.

The terminus of this line immediately adjoins the dam, and the train is there run on to a steam ferry, which in two hours brings it to the western bay called Vestfjord, near the head of the lake—at the entrance to the Vestfjord-dal. The train then proceeds up the Vestfjord-dal as far as Saaheim, 10 miles away.

The dam at Mösvand is entirely of concrete, with flood-gates by which the flow of water can be accurately and at all times regulated. A weir is provided, to prevent the water flowing over the dam itself when the reservoir is full. The building of the dam was attended with considerable difficulties, for it is at an altitude of 3,000 ft. above the sea, which means a great deal in those latitudes, and on the high mountain wilds. About five miles below the Mösvand dam is another dam, forming the intake for the power station. A tunnel of 2½ miles in length and 260 sq. ft. in section conveys the water to a reservoir entirely blasted out of the solid rocks at the top of the southern slope of the valley. The tunnel (to the power station) is in the southern face of the hill, and has a fall of 1 in 300. It was made by driving adits into the rock at certain intervals from outside, and when these had reached the prescribed position, tunnelling right and left parallel with the face of the cliff. The rock excavated was brought out through the adits and forms dumps below, which mark the position of the tunnel. A thousand feet below this is the power station, the water being brought down in ten huge flumes placed together like gigantic organ pipes. The ten flumes are placed on foundations at regular intervals; the mountain side had to be entirely denuded of earth and stone, so that the foundations or beds

Digitized by Google

could be laid on solid rock. The power station is situated on a niche or shelf recessed in the rock, from which there was formerly no means of communication with the other side, where the road lies. As soon as the water has passed the turbines there, it is conveyed by another tunnel about 3 miles in length to a place close to the factories where another fall of nearly 1,000 ft. brings it to Power station No. 2, of about the same size as the first, namely, 140,000 H.P.

The natural surroundings render the work particularly difficult, the whole valley through which the river runs being for several kilometres below the Rjukanfoss a huge chasm with perpendicular sides hundreds of metres in height. Connection between the power station and the opposite side is formed by a suspension bridge of 330 ft. span, the roadway of which is about 330 ft. above the river-bed.

Dwellings for the engineers and employés are on the north side of the valley. The mountains are so high and steep that for months of each year the sunshine never reaches the dwellings.

From the plateau on which the power station and the buildings are situated, the road winds rapidly down to the valley. A railroad blasted out of the very steep hill-side goes from the power station down to the factories at which the terminal station of the railway proper is situated. The line to the power station was built to bring the heavy machinery right up to the power station. There are 10 units of 14,000 H.P. capacity. The turbines, on account of the great height of the fall, are Pelton wheels, and the generators, owing to the difficulty of making such large units, are constructed as double generators.

The most important thing in power stations with so great a fall is the arrangements of the turbines and their regulators, and the flumes which are subject to a pressure at Rjukan of up to 30 atmospheres.

FIG. 4.—THE TYSSE FALLS POWER STATION, SHOWING FLUMES FIXED AGAINST FACE OF CLIFF.

The lower part of the flumes are therefore made of welded plate of great thickness—up to 1 in. The diameter of each pipe is 5 ft. The upper half of the flumes, where the pressure is less, are made of riveted steel plate.

The working voltage is here, as at the Svælgfoss and other establishments connected with Notodden, 10,000 volts, the current being three-phase alternating with a frequency of 50. The power is transmitted through 60 wires, either copper or aluminium, to Saaheim, where the factories are situated. These factories, which, like those at Notodden, are intended for the manufacture of nitrogenous products, cover a large space. Thus, the electric furnaces cover over 86,000 sq. ft.—and the absorption towers a similar area.

At Tyssefalls in the Hardangerfjord, some few kilometres north Odda, there is another station.

The Tysse river has a relatively very small catchment basin, only 1,500 sq. miles, and the river proper has an aggregate fall of 1,300 ft. in a length of 3 miles. The catchment basin is nearly circular, and includes a whole number of lakes which empty themselves into the Ringedalsvand, a large lake. By means of all these lakes an ideal regulation of the water-supply can be accomplished. The Ringedalsvand is particularly adapted for the purpose of a reservoir, as a extra height of about 100 ft. can be obtained, partly by raising the level by a dam, partly by lowering it by means of an artificial outlet.

The primary regulating work has raised the minimum of the discharge, from as low as 35 cub. ft. per second, to 350 or 420 cub. ft. —that is to say, that instead of going down at times to about 4,000 H.P. a minimum of 40,000 of 50,000 is easily maintained.

Owing to the very steep and mountainous nature of the country the difficulties presented in building the pipe-line were, of course, considerable (Fig. 4.) The tunnel is over two miles in length, and is at a height of over 1,320 ft. above the fjord; it was constructed by first driving adits from outside the face of the cliff, and these have in most instances been unusually difficult of access. Placing the flumes or water pipes, and making the foundation for them, was not less

FIG. 5.—POWER STATION, TYSSE FALLS.

difficult. Not only had the bed to be blasted out of the face of a cliff so steep that most of the dislodged fragments went right into the fjord, but some of the flumes lie against a perfectly smooth precipice which rises at an angle of 60deg. about half-way up the hillside for a distance of about 330 ft. It was necessary at first to fix ladders by iron bolts to the cliff, until footholds could be cut in the rock to enable work to be begun at this spot. The laying of the pipes was accomplished with the aid of a Decauville rail track, which was laid from the fjord right up to the discharging reservoir. The trucks were

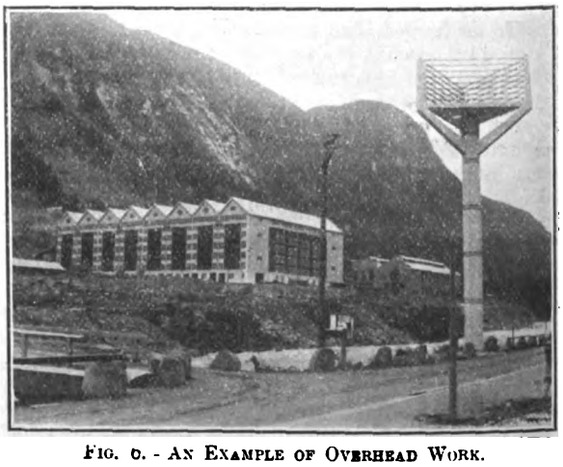

FIG. 6. - AN EXAMPLE OF OVERHEAD WORK.

hauled up by a wire rope, which went over a roller at the extreme top, and which was worked by an electric windlass placed about half-way up the precipitous slope. Notwithstanding the many risks and the difficulties encountered, the entire undertaking was carried out without a single man being injured.

The power station (Fig. 5) contains seven sets of machinery, each of 4,500 H.P. capacity, and the power is transmitted at a primary tension of 12,000 volts by cables on two rows of posts to Odda, where it is

Digitized by Google

used in the large calcium carbide works belonging to the Alby United Carbide Factories, and also by the cyanamide works of the North-Western Cyanamide Co. Some of the power will also after this summer be utilised by the Hardanger Electric Iron and Steel Works, the first in Norway to smelt iron ore and produce iron and steel by the processes patented by the Swedish Elektrometall Co.

In taking the cable to Odda considerable difficulties were also met with, especially the risk of the communication being severed and works thus stopped by avalanches or rocks falling from a very steep cliff, along which the cable had to be carried for a length of about a mile and a quarter. Several such stoppages having occurred the first year, it was decided to pass the cable through a tunnel in the cliff, and this has been accomplished with the most satisfactory result. Further developments are projected for this unique power station (Tysse), which it is estimated will be capable of yielding from 60,000 H.P. to 100,000 H.P. when the water supply has been fully regulated. It is not yet determined to what uses the remainder of the power shall be applied, but both zinc smelting works and iron works have been spoken of, and the enlargement of the power station has been resolved upon.

THE ELECTRICAL EQUIPMENT OF A MODERN THEATRE.

BY D. C. M. HUME.

(Concluded from page 209.)

Lighting.—The first thing that must be noted here is the local regulations, and the best thought out of these are those of the London County Council, who have a special department for this class of work under the charge of experienced officials and inspectors. Great care is thus taken of the safety of the public.

Under the L.C.C. provision has to be made whereby all danger or "police" lights, &c., are fed from a special intake from other mains than those supplying the auditorium and stage. The reason for this is to ensure lights at all the exits should a failure of the main supply take place and a panic ensue, this in addition to the alternative lighting agent of gas or oil which is likewise compulsory. This regulation applies to the exit signs in a theatre, which signs must be easily seen, of a certain size of letter, and on no account extinguished during the time the theatre is open. Owing to the large load that a theatre represents, it is usual to take in the three-wire system at each intake and balance the theatre as a whole.

This enables the consulting engineer still further to safeguard the public, as he can arrange all foyer, passage and "police" lights on alternate wiring off the one intake, balancing them independently on this intake.

The main intake is usually situated on the stage side of the proscenium, and the best theatres have a stand-by change over in case of failure of supply. The company that has the greater part of London's theatres—the Charing Cross Electricity Supply Co.—have a special theatre mains doing nothing else, which arrangement is most necessary when one considers that any theatre may switch on or off a total load of some 30 kw. The Charing Cross Company use a battery on these mains, and can take a sudden load of 3,000 amperes on or off without dropping the network volts. It is such an arrangement that permits Drury Lane, to have dark changes, in spectacular pantomimes without loss of popularity in the neighbourhood of brilliancy in the production. It is a curious load that is provided by theatres, and it is interesting to see machine after machine started up from 7:15 to 7:45 p.m. every evening at the various stations and sub-stations of theatreland.

From the stage intake it is preferable to balance the stage against the auditorium where possible, thus obviating the nuisance of having three wires on the stage, but sometimes, as in Glasgow, for instance, this is not permitted by local regulations and makes the stage wiring rather complicated and the switchboard a source of joy to the designer.

Stage Lighting.—Stage lighting may be divided into two halves, incandescents and arcs. The principal illumination is derived from a solid square frame of lamp banks arranged round the proscenium and directed towards the stage. This frame consists of the float or footlights on the ground, proscenium lengths at the side, and No. 1 batten behind the first "border" or masking "cloth" above. This system is reduplicated, with the exception of the ground lights, once, twice or thrice according to the size of the stage, the side lights being supplied by wing ladders or side lengths hung on the back of the scenery wings. The battens or overhead lights usually diminish in length and capacity as they get up the stage. The record batten is 55 ft. four-colour, namely, No. 1 at the Coliseum.

In the ancient days, gas bunch lights were used in the wings, consisting of a cluster of burners in a circular reflector. Similar electrical fittings are only used in modern theatres for special effects of local lighting. Electric bunches were also employed around the circus ring at Liverpool Olympic, but did not find favour except for spectacles, &c. The main lights of the building and vertical arcs from a "lime gallery" directly above the ring light up the arena as well as anything.

Provision has also to be made for additional effect lights, floor lengths, &c.

The float runs the whole width of the stage, and is generally wired on three circuits, but in theatres where spectacle and magnificent productions are expected, the proscenium lengths and No. 1 (and sometimes No. 2) battens and the float are wired for four circuits, which can be lamped up in colours as required. A common arrangement is white, amber, red and blue (or green).

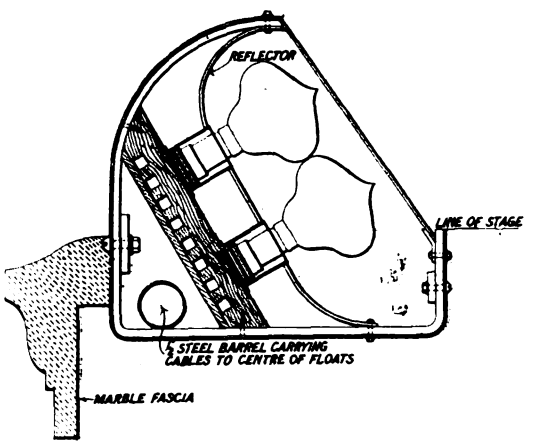

FIG. 6.—SPECIAL 4-COLOUR FLOAT AT THE LONDON COLISEUM.

The float should be arranged in an iron trough fitted with lids for use in the day time when the dust is rife and people and things are apt to pass over it. A good white enamel background is as good as anything. Glazed brick does not keep its colour, nor sheet tin its polish. Lamps should be arranged to give their best light to the stage though they are often installed in exactly the opposite way, *i.e.*, with the point towards the performers. A successful lamp, though expensive by reason of not being a standard pattern is the T lamp with two filaments. This makes a very neat and small float, the latter attribute being especially advantageous, as this is one of the most obvious of the lighting apparatus from the audience's point of view. An error is often made in trying to obscure the end by sinking the float in a bevelled trough which, though taking it down out of sight, often produces a hard shadow about 4 ft. up the back cloth. The float is best wired from the centre in either direction, with each circuit alternately wired from two distribution boards. Fig. 6 shows a four-colour float and Fig. 7 an arrangement of battens.

Proscenium and side lengths follow the float in general construction. Side lengths, by reason of not being permanencies, are made up on wood bases and protected with a netting cover from exterior damage. The floor lengths may be conveniently and cheaply made up of heavy casing as a base and small vertically projecting pieces, on either side of which is mounted a batten-holder to take the lamps which thus lie end to end along the length.

Digitized by Google

The float and proscenium lights are permanent, but the battens, wing ladders, floor lengths, &c., are subject to constant change of position, and must, therefore, be fitted with a removable connector, and for this reason, even in the longest of battens (Coliseum 55 ft.) all wires are brought out at one end ready to make off into plugs.

Stage plugs are of several designs, and perhaps the best is the Bowles type (Fig. 8), in which the actual contacts are of an ordinary knife switch design and very positive. It is impossible to put these plugs in wrong with reversed poles, &c., because the male portion slides into grooves in the lid of the plug-box, and must be introduced therein before the box can be closed and contact made. The lid has a snap fastening, and an accidental pull on the lead does not pull out the plug. Another point about this plug is that it can be made to accommodate a number of circuits in one plug. The plug can also be used for main batten connections, which are placed on a rule as the fly floor. The box itself is of iron and asbestos lined. Contacts are of ample surface, well separated and protected. The Siemens plug is of smaller dimensions and when installed at an angle is possibly easier to connect. In this, the male portion is held in position with a pistol catch to prevent premature disconnection.

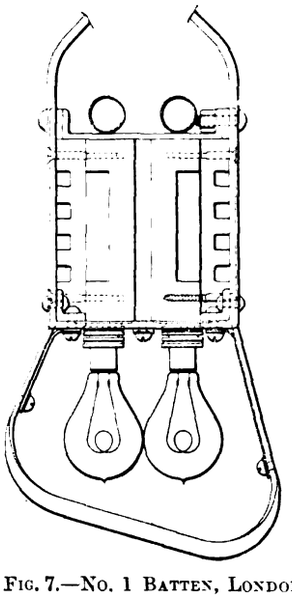

Fig. 7.—No. 1 Batten, London Coliseum.

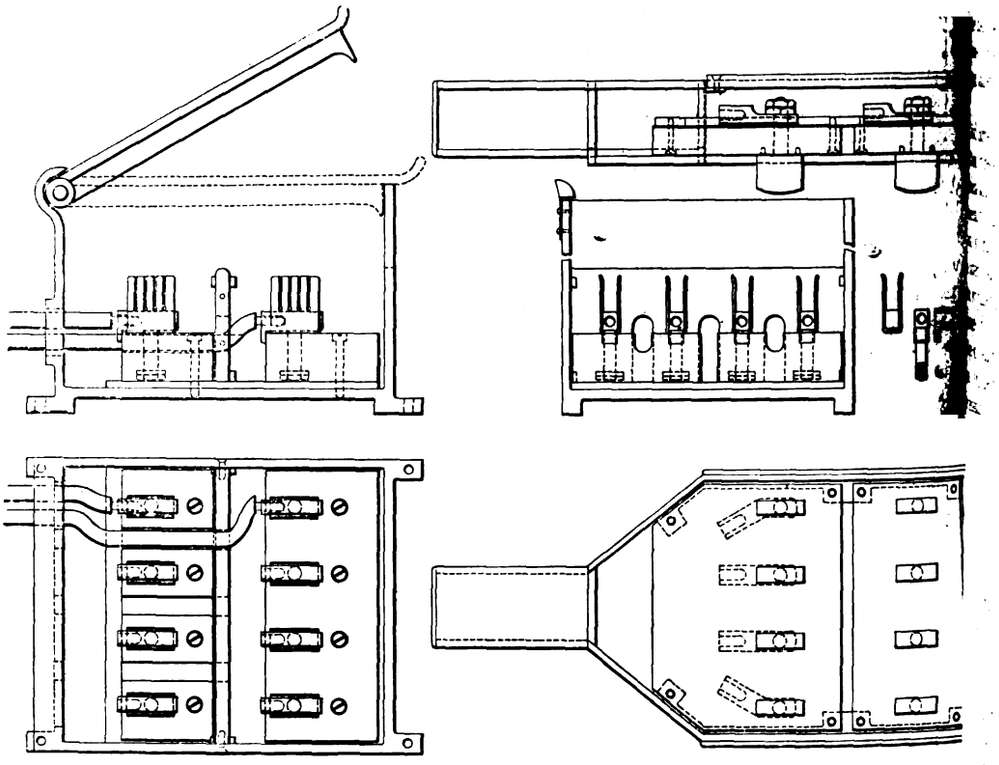

Fig. 8.—The Bowles Stage Plug.

Other designs are of the two-pin and concentric types, the poles being kept distinct in the former by making the pins of different lengths. This distinction of poles is necessary because of the stage level arcs which take their supply from plugs.

At the Chelsea Palace both the two-pin and concentric types are to be found, the former being on the alternating supply and the latter on the direct current supply, both of which are installed on that particular stage.

Stage plugs are situated preferably in cast-iron boxes just beneath the stage level, and are reached through a trap in the boards, known theatro-technically as "dips." At the London Coliseum, owing to the revolving stages, plugs were impracticable, so a plug truck was made (an illustration of which we give in Fig. 9) which carried a four-colour master plug; this could be plugged on to a central point under the middle table of the stage, the truck acting as a distribution board for the stage surface.

Battens, float, proscenium and side lengths, &c., have to be wired in two, three or four circuits according to the ambition of the theatre, so that colour effects can be produced accurately. Nos. 3, 4, &c., battens are often left single-circuited or double lamped. The most ambitious theatres, such as Drury Lane, Covent Garden, Coliseum and the New Theatre, are wired with four circuits practically throughout, and this allows of great latitude of effect when lamped with white, amber, blue, red, or great brilliancy when lamped two white, one blue, one red, &c. Where very great brilliancy is required, such as in ballet lighting on occasion, recourse has been made to double battens—*i.e.*, two white battens back to back. This has been done at the Alhambra with great effect.

A word on the colour of lamps. A metal filament gives a very bright light, but in the opinion of the writer this is somewhat white for uses other than big stage spectacles; carbon lamps are better except on low voltages. Another point is that owing to the breakage of filaments under the rough usage theatre lamps receive, it is the number of lamps per year that counts with theatre work. As to tints, amber should be decided and free from red or brown. Blue should be a good ultramarine or cobalt and not turquoise or violet or green whilst red should be a rich ruby port colour. Any of these, of course, can and should be varied to suit the particular production on hand. "Dip" lacquer should be avoided where possible except for temporary effects; a good stained glass lamp keeps its colour always, whilst dip is uncertain of colour and apt to burn or peel off. The only objection to stained lamps is the price. Dip is cheaper but it is the greatest mistake to use a cheap dip which either peels off or burns light.

Switchboards.—In many theatres this conning tower of the stage is all too inadequately provided for, being put in any odd corner by the inconsiderate architect, or cut down to the minimum size by the stage manager rapacious of room for his productions. We have in mind such boards as the Gaiety, Hippodrome (old board) and the Alhambra; in contrast with which we may cite such boards as Covent Garden, the Coliseum, Drury Lane and the New Theatre. The last of these is a very fine board, but it is somewhat at a disadvantage by reason of its installation in the prompt side flies, some 25 ft. above the stage. The result is, the electrician is dependent on bells, telephone and pilot lamps, and cannot judge any niceties of effect from his board.

Digitized by Google

The largest board in England is the Coliseum, including stage controls; next come Covent Garden and Drury Lane and the Palladium.

A theatre board is best arranged in three main panels—stage, dimmers and house—which in themselves are best arranged as follows: The stage board carries all switches relative to the stage lighting and only these. All 'bus bars, contacts and switches should be on the front of the board, except in isolated cases, and switches should be arranged in horizontal lines according to circuits or colours. Thus a four-colour board has five rows of switches—*i.e.*, four colours and one row of special effect switches. Circuit switches controlling the same points should be arranged vertically above one another, as the board must be so arranged that the electrician knows by instinct where his switches are. Thus, float white, amber, red and blue blinding lights (dark change lights shining straight at the audience, usually lamped red) will all be arranged vertically above each other. On the end of each row should be mounted a main switch controlling that row by which a "black-out," or total extinguishing of all lights, is instantly effected. These mains should be placed on the end of the board nearest the stage, and may be mounted on a separate panel with advantage. There is no necessity for any meters on this board, but any point out of sight of the board should be indicated thereon by a pilot light. Main switches *must* be of a quick break sparkless type or the green flash is seen all over the darkened theatre. Plain cartridge fuses or other clean-blowing fuses under thumb nuts should be used, and every switch and fuse should be clearly labelled.

The dimmer board carries the necessary gear for dimming the lights with some form of resistance, and so providing means for many beautiful effects and blends.

Dimmers are generally of the two types—metallic and liquid. The former consists of ordinary resistance coils and rheostat switches, and the latter of salt solutions acting as water resistances and operated by pulley gear or the like. For the former there is the advantage of economy of room and mechanism, with the disadvantage of inelasticity of adjustment; in the latter the converse obtains. On the whole, from the producer's point of view, the liquid resistance is much the better owing to its flexibility.

The ordinary wire dimmer consists of coils of wire strung on frames in the usual way, or embedded in porcelain enamel. About 30–50 terminals should be provided to give proper regulation, for anything in the way of a jerk in the lights is to the producer as a red rag to a bull. The regulating switch may be of two kinds, the simple rheostat type (Alhambra and Empire switchboards) or the wheel type of control (Gaiety). In the former the contacts are usually vertically arranged as radial double clips into which slides a knife switch pivoted on a horizontal bar running across the board. In the latter, cable gear operates a sliding contact on the coil banks situated above the board in special fireproof cases. In any type of dimmer, the resistances have to be, by local and L.C.C. regulations, installed in a fireproof room or chamber by themselves which is fitted with a self-closing door. It is best to put the fuses on the resistance circuits in this room as well.

Liquid resistances are usually of the Lyons type, which consists of long cylindrical earthenware pot, not unlike a common drain-pipe section, in the base of which is fitted a truncated cone of copper, a connection to which passes through the side of the jar through a rubber bung cork. Above this fixed terminal is arranged the movable terminal consisting of a vertical copper rod about 6 in. or 8 in. longer than the dimmer pot, the lower end of which is fashioned into a hollow cone registering exactly on the cone of the fixed terminal at the base of the pot. This rod carries a terminal screw at the top and can, by means of suitable pulley gear, be raised or lowered in the pot at will. The jar is filled with a 10 per cent. solution of common salt, which does not corrode the case, but gets rather hot. At 1 ampere per square inch of plate surface the voltage absorbed by such a resistance is 1 volt per $\frac{1}{10}$ in. of electrolyte between the plates. This is a useful approximate formula. A special salt is produced by the makers of dimmer gear which has the advantage of not getting too hot or bubbling unduly. The most improved dimmer pot has no bottom contact, but the pot is made double, and a copper strip runs from the cone at the bottom up between the two sides of the pot, and so provides a terminal at the top, and thus prevents any possibility of the liquid leaking out.

The design of a dimmer gear does not consist in producing a mere winch wheel, but arrangements have to be provided so that any individual circuit may be dimmed separately or the whole dimmed to darkness from various positions of individual dimmer wheels. Thus, proscenium, float and No. 1 batten ambers may be on full, and whites three-quarter dimmed, Nos. 2, 3 and 4 battens red full, No. 5 batten and floor lengths red and blue half dimmed. It is then required to fade out the whole scene or gradually produce a sunset effect, &c. It is clear from this that provision must be made for dropping the individual dimmers in either of their extreme positions, the common shaft on which they are mounted continuing to operate any dimmer not in one of such positions.

This is very efficiently effected in the mechanism of Messrs. Moy & Bastie, in which the horizontal main shafts are operated from a hand wheel gearing with a worm gear which ensures an even and fairly slow effect. Each individual dimmer wheel (around the circumference of which runs the pulley cable) carries, however, a small radial handle by which it can be individually worked. On the main shaft on each side of every wheel is fixed a rachet, the one on one side being right-handed,

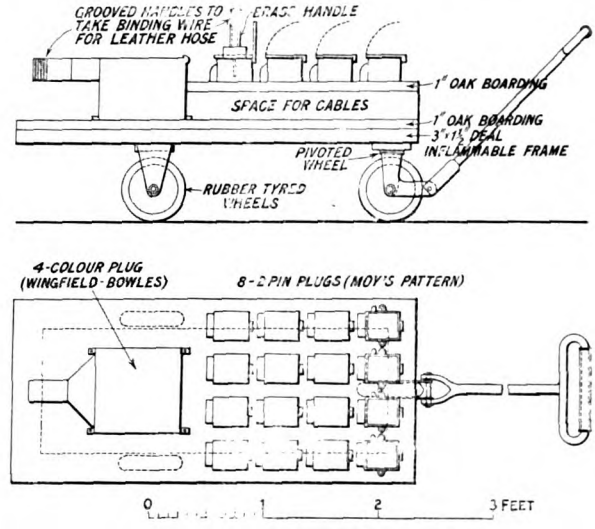

FIG. 9.—PLUG TRUCK, LONDON COLISEUM.

and the one on the other left-handed; the wheel itself is free upon the shaft. Mounted upon one spoke of the wheel are two small pawls which normally engage upon the aforesaid rachets, thus locking the wheel to the shaft in both senses of rotation. When, however, the dimmer wheel is turned to its extreme position, it is necessary to unlock it from the shaft and this is effected by means of a small stationary inclined plane fixed upon the panel of the dimmer board; this receives the extended arm of the pivoted pawl, and is so set as to raise it clear from the rachet and free the wheel in that sense. Meanwhile, the rachet and pawl on the other side of the wheel and locking it to the shaft in the other sense of rotation remains in action, so that a reversal of the main shaft picks up all the wheels again at once whatever their individual positions may be. These dimmer wheels carry two laminated switch contacts which serve to short-circuit the dimmer pot in its "all-out" position, thus saving unnecessary heating of the pot and liquid, and giving the full voltage to the lamps. To operate one dimmer by itself it is necessary to trip the pawl by hand. Each dimmer should be fitted with a pilot lamp at the top of the dimmer board, and this lamp should have a tumbler switch to itself.

A similarly acting mechanism depends on the action of a jambing screw with a quick pitch thread, the nut of the screw coming against a stop in the extreme positions, and so unscrewing a quarter turn and disconnecting the wheel.

Digitized by Google

These gears can be applied to wire resistances if the step contacts be arranged suitably.

There is another type of liquid resistance which has, however, not been received very enthusiastically by reason of the fact that it necessitates the actual resistance being upon the board. In this type a sector-shaped earthenware tank is provided, through which a radial plate sweeps when operated by the handle rigidly attached thereto. The idea of this device is to eliminate the dimmer room as a separate chamber, but this is a doubtful advantage.

The house board is a simple switchboard, and should always be installed if possible on a separate panel to the main board. It carries switches controlling the ceiling lights in the auditorium, the balcony and circle fronts, &c., in fact, all lights in the auditorium other than those coming off the "backs" board—that is, under balcony points, back walls, &c. The auditorium board has a main switch controlling the whole, and should, therefore, be installed as near as possible to the main stage board. In a small theatre it may form part of this with advantage. All stage boards must carry cartridge fuses for each switch.

Before leaving switchboards, mention must be made of the board installed at the Glasgow Coliseum (Fig. 10), which is unique in that it is a three-wire board in which the two sides are kept 6 ft. apart according to regulation, and yet one man can work the board as easily as if it were a one-pole board. This is effected by mounting all the live switchgear on the back of the board, which stands out 3 ft. from the wall of the building. The switches are of the claw type, and are operated by an insulated rod running through the board slate and terminating in a mushroom head of ebonite on the front side. The right-hand panel of the board takes one pair and the left-hand panel the other, and between the two panels is a rigid uralite permanent builder's partition. Thus, the distance of any live part of the one panel to any live part of the other has to be measured up and over and down this partition, whilst the actual operating knobs are but a foot apart in some cases.

Into each knob is let a small stained ivory disc showing the colour of the circuit it controls, the name thereof being on an ivory tablet on the slate itself. This board looks exceedingly neat, and is fast to work. It was designed by Mr. E. Wingfield Bowles, the theatre Consulting Engineer, and was made by Messrs. Blackburn & Starling, of Nottingham.

Idealists have advocated an electrically operated switchboard from a keyboard in the auditorium. This, whilst giving the engineer excellent scope for providing beautiful effects, is scarcely feasible in the average theatre.

All the stage passage lights, dressing rooms, &c., are best controlled from the doorkeeper's lobby on a special distribution board fed direct from the intake.

Arcs.—The other section of stage lighting is the arcs. These are arranged as a rule as follows: Half way up each side of the proscenium there are two or more arcs—"perch arcs"—up on the fly-rail arcs as required. In some theatres (for instance, the Gaiety) a special fly arc gallery is provided; this is a good idea which allows the fly rail arcs to cover the whole stage instead of having to shine down between cloths, &c., hanging in the flies. On the stage level portable arcs on stands are required. Special stage plugs are installed for this service as a rule, and it is well to use different patterns of plugs for the arcs and incandescents respectively. Plug points are arranged at every arc position and resistances are permanent, installed for choice with the arc fuse boards in a special fireproof chamber. Very large stages sometimes have arcs across the flies (for example, His Majesty's Theatre, where they are across the proscenium arch, and the Coliseum, where they are on the bridge about half way up the stage). The lamps themselves need to be hand fed, and should be provided with boxes which must be light-proof at the joints, as a stray beam of searching white light cannot be countenanced on any self-respecting stage. Such boxes must be fireproof a lined with uralite or asbestos, and so made that a droppi spark is impossible. In the front of these boxes are placed t colour screens made of glass or other suitable medium, a behind them is located the lens when in use. When the lens not in use a piece of plain glass should be used to protect t screen if not of glass.

A shutter is a useful accessory to any lamp as it permits instantaneous "blacking out" for dark changes, &c. T may either be a cut-off or a mask disc between the arc and t lens.

Arcs are not necessarily switched at all, but if desired to they should be controlled from the stage board on a separ panel. If the Bowles plug is used it forms a switch in its though a master arc switch should be provided near the thea main switch, which latter should, in common with the thea main fuses, be kept under lock and key in charge of electrical engineer.

With regard to lenses, these must be good; the cheap l gives an unsightly beam with ringed rainbow edges, and

Digitized by Google

tracts from the spectacle more than it helps it. A good lens is achromatic; it costs a deal of money comparatively, but it is worth it in effect.

All plain lenses are subject, however, to one great drawback: they have an edge, and a great ring of light is shown round the objective, which effect is highly inartistic and positively crude in dark scenes. This may, however, be overcome and the simplest and, at the same time, the best relief to this trouble is the device invented and patented by Mr. G. A. Applebee, of the Grand Theatre, wherein a piece of mica is arranged between the arc and the lens, and has the effect of taking all the edge off the "spot" or "focus," and converting it from a bright spot into a bright place on the stage, and giving it a softness without loss of power.

Nowadays in music-halls we have the biograph to deal with, and it may make its appearance in the theatre proper ere long. This must be installed as low down as possible in a fireproof room, and will require to have its own adjustable resistance therein. This circuit should be provided with fuses up to about 100 amperes, dependent on the throw required. In this circuit there are many special conditions to comply with peculiar to the cinematograph alone.

A unusual feature, and one peculiar to the type of building, are the arc galleries of the Liverpool Olympia, Manchester Hippodrome and the London Hippodrome; these are square boxes in the very roof of the building shining downwards upon the arena directly below, a throw of about 100 ft. There is a practice nowadays of using focus lights from the back of the gallery, &c. One of the first theatres to use this was the King's, Hammersmith. It is a laudable attempt to eliminate or minimise the twin attendant shadows of the perch arc. The London Coliseum tried horizontal front arcs, but they were abandoned after some months' trial in favour of the gallery arc.

It is impossible to give any details about fittings, as it is a matter of taste, but in general it is best to sacrifice magnificence of effect and to spread the lights (see Coliseum tier lights and St. James' roof lighting). So far interior arcs have not been employed, save in concert halls, but the flame arc has certain claims for recognition in connection with this work and would repay investigation; for outside lighting they are undoubtedly the only light.

The author feels that the above notes are somewhat sketchy. It is impossible, however, to describe adequately so general a subject as lighting and power in theatres in a short article of this nature; nevertheless, he hopes the reader will have gained some slight insight into what is really a very interesting branch of electrical engineering.

The author is indebted to Mr. Wingfield Bowles for his courtesy of the loan of several special drawings for this article.

THE MECHANICAL DESIGN OF INDUCTION MOTORS.*

BY H. L. SMITH.

Abstract.—The author deals with the various parts of induction motors individually, and discusses the points that have to be borne in mind in the mechanical design of these machines. Slot dies, punchings, base plates, frames and shields, bearings, belt pulleys and binding bands are considered.

Reference is first made to the importance of getting work through the shops. The author then discusses slot dies, and emphasises the importance of being perfectly definite in the terms used, such as the width of slot. The dies for punching the centres of core plates are costly, and when designing a line of machines a selection of dies should be formed at suitable intervals, and the core plates designed to suit a die from this selection. Here a large firm has the advantage over a small one, in that it can afford to arrange its series at suitable intervals. The diameters of the various sizes of stators should be arranged in regular sequence, so that the same punchings used for the gap of a large machine can be used for the gap of a small one, the gap in the stator being the even dimension, and the allowance for air-gap being put on by circular-turning the rotor core plates.

*Abstract of a Paper read before the Rugby Engineering Society.

Stator Frames.—The guiding principle to be borne in mind when designing any machine like an induction motor, or a machine tool in which there are quick revolving parts running in a stationary frame, is that the frame should be of cast iron and massive to resist vibration, and the revolving parts should be of wrought iron, mild steel, or similar material, and light. Applying these principles to the several parts of an induction motor, we see that (1) the frame should be cast iron and massive; (2) the end shields should be cast iron and massive, the ends being a flat plane and not an oblate cone; (3) the shaft should be of ample diameter; (4) the stator flanges should be ordinary cast iron and massive, never malleable cast iron; (5) the rotor flanges should be malleable cast iron or even steel where necessary, and light; (6) the spider, being a part revolving at less peripheral speed than the flanges, can be ordinary cast iron.

The side of the stator frame near the bottom on each side should have a thick pad cast on inside for taking the terminal box, and, in order to facilitate quick delivery, it should be so arranged that the frame can be put in hand straight away, without having to wait for the arrangement of the terminal box to be finally fixed up.

As regards the important question of cost, it should not be lost sight of that a strong casting is cheaper to machine than a light one, because it can be gripped in the jig more firmly. A light casting in the machine shop is a thing which has to be put up with, and should be employed only when the engineering conditions demand it.

Base Plates.—In order to avoid any confusion in the terms used, it is convenient always to refer to the bearing at the collector end of the machine as No. I., the bearing at the driving end as No. II., and the outboard bearing as No. III. Also, in making the drawings for a line machine, it is a useful convention to put the No. I., or non-driving end, at the left-hand side of the paper throughout the series.

It is possible to recognise three grades of elaboration in design—viz., (1) the simple monolith, or plain plate style; (2) the rolled steel joist; and (3) special for large structures or high-speed work. The general characteristics of these grades of designing as regards castings are as follows: In Grade I. the patterns are cheap to make and there is less slicking of the mould in the foundry; but there is more material used. In Grade II. the cost of the patterns is greater, also the cost of the moulding per ton of material; but the castings may be 10 times as strong, and leave the mould often as straight as a die, and therefore in a condition more likely to promote cheap machinery. Also, the castings being stronger, they can be held more firmly in the machine without fear of springing, and hence, as often as not, the extra slicking of the mould is offset by greater ease in machining. Generally, Grade I. of design would be used for stationary parts, or when there is only one article required off the pattern; Grade II. for ordinary running parts, or when there are a fair number required off each pattern; while Grade III. would be used when the speed is high or for repetition work, when the number of articles is so great that the cost of the patterns becomes negligible in comparison.

It is a matter of common knowledge that a rolled-steel joist is much stronger to resist a direct load than one applied laterally, and yet the section of the ordinary base plate is that of a channel iron turned on its side with the web uppermost; or it may be compared to a flanged beam with the upper flange enormously increased and the lower flange removed altogether. The result is that such base plates sometimes leave the foundry warped badly, requiring machining pads ¾ in. thick. It is only in the case of heavy work ordinarily that a base plate is provided with lower flanges. The provision of a lower flange has also the advantage that it reduces the pressure on the concrete foundations. This pressure, in any case, should not exceed 4 tons per square foot, and if it can be arranged to be less than this so much the better.

The author gives a "basis design" for a long, simple base plate for a third-bearing machine, and believes that the base plate, being a stationary portion of the machine, and not standardised to any extent, should in general be designed on Grade I. lines and massive; but this depends to a certain extent upon the destination—*e.g.*, if a machine has to go to Japan, the design of the base plate would be on Grade II. lines, and different from what it would be if it had to go only to Coventry.

Shafts.—An important point to be borne in mind in designing shafts is that, since turning is one of the cheapest of manufacturing operations, and the shaft in point of peripheral speed comes within the slow-moving category, it should be of ample diameter.

The amount by which the spider is thrown out of centre owing to the deflection of the shaft due to the weight of the rotor is dependent to a certain extent upon the class of fit of the spider upon the shaft. If the spider is a heavy force fit upon the shaft, then the portion of the shaft inside the spider hub becomes one solid mass with the latter, and so is not included in the effective length of the shaft subject to deflection. If, however, the spider be not such a good fit upon the shaft, and be considered to bear hard at two points,

Digitized by Google

then between these points the bending moment is uniform and equal to the maximum, and that part of the shaft is bent into an arc of circle. By deducting this length inside the spider hub from the total length between the centres of the bearings we get the effective length of the shaft subject to deflection for an average case.

Considering this, the author calculates that the deflection is given by $\frac{0{\cdot}021}{10^6} \cdot \frac{Wl^3}{D^4}$, where W = weight of rotor in pounds, D the diameter of the shaft in inches and l its effective length. The shaft is usually designed so that the deflection due to the weight of the rotor alone should be about 7 per cent. of the air-gap, and to this deflection has to be added the extra deflection of the shaft due to the magnetic pull, also the deflection of the stator frame, both of which are uncertain quantities and difficult to calculate, so that the total deflection comes to about double the deflection calculated above for the weight of the rotor alone.

In order to reduce the risk of the portion of the shaft under compression receiving any permanent set during the operation of forcing the shaft into the spider, it is advisable to arrange for the full pressure to come on only at the final forcing of the spider into position. By arranging for the spider to be a sliding fit at the start the length of shaft under compression is reduced, and the shaft is in the position of being a column with the base rigidly fixed, thus again increasing the strength. This arrangement can be simply effected by the following device: It is the custom in large manufacturing concerns for the allowance for the fit to be left on the shaft, the hole being the even dimension; but there are certain necessary exceptions—*e.g.*, the force fit for a coupling is different from that for a pulley, and seeing that it is not known until the last moment whether the machine is to have a pulley or a coupling, the only way in this case is to make the shaft the even dimension and to allow for the fit on the pulley or coupling. On the other hand, in the case of a spider, ordinarily the hole would be the even dimension and the allowance on the shaft.

The shaft would be gripped by a special hollow mandrel hydraulic press, which would take hold of it close to the neck, hold both shaft and spider concentrically, and force the shaft direct into the spider. With such a machine it would be possible for the large expensive keys at present used to be reduced in size by one-half; and this is where a large firm has the pull over a small one, in that a small firm cannot afford thousand-ton hydraulic presses, and often not even proper grinding machines for differentiating easily between the various fits.

End Shields.—The outstanding features in the design of an end shield are (1) that it may be massive, being a stationary portion of the machine; and (2) that it may be designed on the Grade I. style—*i.e.*, on simple monolith lines, if tight for room. The shape of an end shield, especially that portion of it which shrouds the stator winding, is governed by considerations other than those purely of mechanical severity. From its very nature it must be a combination of bent struts and crooked tie rods in cast iron. If the design with a certain thickness of material looks too weak, it may be reinforced, if economy of space is essential, not only by ribbing it up, but also, alternatively, by increasing the thickness of the metal.

The redeeming feature of the Grade I. style of designing is that it conduces to ease in moulding, and this cheapness of moulding may offset any extra weight of metal required.

The great advantage of employing end-shield bearings over pedestal bearings and protection caps is that the former, having only a single plate beyond the stator winding, do not necessitate so long a shaft, thus improving deflection. For instance, the shaft of a motor designed to give 50 H.P. at 720 revs. per min. had to be lengthened exactly 6 in. to accommodate pedestal bearings and protection caps in place of the usual end shields.

In the case of explosion-proof motors the ribbed style is necessary, because there the ribs are used to dissipate the heat. The ribs would be all on one side of the end shield, and seeing that cast iron is six times as strong in compression as in tension, this points to the conclusion that the ribs should be on the inside and in compression, while the plate should be on the outside and in tension, especially as the heat is conducted away equally well whichever side of the plate the ribs are on. The explosion of marsh gas and air may rise to 130 lb. per square inch, and the end shields and collector cover should be designed strong enough to resist this. Under the influence of the explosion, the end shield tends to assume a spherical shape. Those portions of its contour which shroud the stator end windings, and which are, or should be, already spherical, are in pure tension. If they deviate from the true spherical form, they are by the amount of such deviation subject to compound stresses, analogous to those in a crooked tie rod under a load due to gravity. If truly spherical, and therefore in pure tension, they do not need any ribs, while, as regards the flat plate which forms the end of the end shield, the ribs should be on the inside and in compression. On the outside they are a source of weakness rather than of strength. If a flaw occurs in the thin rib it does not matter in compression, whereas in tension it is like the weak link of a chain. The flange where the end shield is bolted to the stator frame can be ribbed externally to the spherical portion of the end shield, or it can be made thick enough to stand on its own merits. The straining actions on an explosion proof end shield are exactly opposite to those on an open-type end shield. In the former, it is the flat plate at the end which requires special attention, whereas in the latter it is the curved portion round the stator end windings.

Bearings.—From an engineering point of view the bearing at the driving end should be about three times as large as the bearing at the small end; but from a commercial point of view they should be the same size at each end, so as to be interchangeable. The question whether to make the bearings the same size or not may be answered by saying that for small machines the commercial aspect should be predominant, and for larger machines the engineering; where to leave off is a matter for judgment.

In rope-driving third-bearing machines it makes a convenient arrangement to have a coupling between the rotor and middle bearing, close to the latter, so that the rotor can be removed without dismantling the rope drive. The shaft in this case is in the position of being a "continuous beam," and the coupling ought, properly speaking, to be at the point of contrary flexure, but it is usually more convenient to place it close to the middle bearing. In working out the bearing pressures for such a case, the addition of the loads due to the pull of the ropes and the weight of the rotor respectively is vectorial.

In designing ball bearings provision has to be made for the rotor to take up its position at the magnetic centre of the machine, which does not always coincide with the geometrical centre. The maximum variation that is likely to occur in practice may be taken at $\frac{1}{8}$ in. on either side of the geometrical centre line.

Belt Pulleys.—In determining the width of belt necessary to carry the given power, we have that the useful pull in pounds ($T_1 - T$) multiplied by the velocity in feet per minute (V) = the foot-pounds of work done per minute. The breadth of belt required depends also on the loss due to centrifugal effect at high speeds and on the diameter of the pulley when the latter is small, so that the formula may be written in the form $b = k_1 k_2 k_3 k_4 HP/V$. The different values of the multipliers are given in the Paper in four tables.

The author finally gives an example of the method of calculating binding bands.

PHYSICAL SOCIETY.

At the meeting held at the Imperial College of Science on May 12th Prof. H. L. CALLENDAR, F.R.S., president, in the chair,

"Diagrams of Stream Lines past an Elliptic Cylinder"

were exhibited by Sir GEORGE GREENHILL and Col. R. L. HIPPISLE and a Paper on

"The Method of Constant Rate of Change of Flux as a Standard Determining Magnetisation Curves of Iron."

by J. T. MORRIS and T. H. LANGFORD, was read by Prof. J. T. Morris.

The research described was instituted with the object of finding what differences there were between the magnetisation curves for a given sample of iron when determined (1) by the older methods in which the flux is changed suddenly, (2) by a method in which it is changed exceedingly slowly and at a uniform rate.

The methods experimentally examined were:—

1. Method of constant rate of change of flux.
2. "Slow cyclic" hysteresis loops by method 1.
3. "Step by step" magnetisation curve.
4. "Step by step" hysteresis loops.
5. Method of reversals.
6. Alternating-current magnetisation curve.

Details are given of the theory and practical working of method 1. In this method the magnetising current is continuously increased through a primary winding by a specially designed resistance at such a varying rate as to maintain a constant voltage generated in a secondary winding. A certain amount of skill is required in operating the resistance, but an average experimenter may easily acquire it with a little practice. The complete change of the current occupies times varying from one up to some five minutes.

Tables are given of the magnetisation curve determined by the different methods at a number of values from H 0·3 up to 70·0, and of the permeability from B 500 up to 17,000.

At low values of the magnetising force the uniformly varying

Digitized by Google

method gives results of some 200 lines per square centimetre in excess of the older methods.

As regards the time required for determinations by the various methods experimentally examined, ballistic methods are undoubtedly the most tedious. The alternating-current method (method 6) has considerable advantages in this respect, a full set of readings of magnetising current and induced voltage occupying a very short time. When, however, it is necessary to take oscillograms at various points in order to plot curves of form factors, the time required is enormously increased. The method of uniformly-varying flux (method 1) is peculiarly adapted for use where time is a consideration, and at the same time a high degree of accuracy is desired. A complete magnetisation curve may be taken in a very few minutes, and the mean of many such curves obtained in, say, one hour, the iron being demagnetised between each test.

The method of "uniformly varying flux" appears to possess advantages, both scientific and practical, over the older methods in use for the testing of ring samples of magnetic materials. It avoids difficulties due to eddy currents and magnetic viscosity, which effects are themselves due primarily to rapid or irregular changes of flux. Besides rapidity of experiment it also has the advantage of accuracy of operation under standard or predetermined conditions of magnetic change.

The method is, therefore, commended for the carrying-out of magnetic tests, especially where great accuracy under definitely known conditions of experiment are essential.

DISCUSSION.

Mr. A. CAMPBELL remarked that it was rather difficult to say whether the tests made with a slowly varying flux that were required in practice. He thought tests made with cyclical changes were more useful. The differences in the results given by the two methods were important. He pointed out that the method could be used for the determination of iron by substituting a known mutual induction for the iron under test.

Dr. A. RUSSELL pointed out that the value of H was different at the inner and outer radii of the iron ring used by the authors.

Dr. S. W. J. SMITH said it would have been interesting and instructive if the authors had performed a similar series of experiments by the ballistic methods upon some material freer from magnetic viscosity than iron. Experiments made upon a sample of nearly pure iron in weak fields did not seem to be explicable along the lines suggested by the authors for the iron they used.

Prof. C. H. LEES drew attention to the extraordinary simplicity of the magnetisation curves. It looked as if $1/\mu$ were a linear function of H.

The PRESIDENT remarked that by superposing on the constant magnetising field an alternating field which was gradually reduced to nothing, the larger values of the permeability were obtained. For weak fields this was over 1000000. This effect was due to the residual magnetism left by the alternating field.

Prof. J. T. MORRIS, in reply, stated that they had not tried their method with widely different speeds. In reply to Dr. Russell, he stated that the inner ring was tested by the different methods. Replying to Mr. Campbell, he had thought of the present method as a means of measuring mutual induction.

The PRESIDENT gave a demonstration of the action of the electric temperature regulator designed by him for experiments by the continuous electric method on the specific heat of water in 1897, and described in the Phil. "Trans.", A., 1902. The expansion of liquid in a bulb causes a thread of mercury to make contact with a platinum wire, closing a relay which puts a 16 c.p. lamp in series with a similar lamp in the regulator tank. If the wire is fixed, hunting occurs owing to the mercury sticking to the wire and to lag of the heating bulb. This is prevented, either by causing the wire to move slowly and continually through a distance of about 1 mm. with a period of 5 to 10 seconds, or by fixing the lamp bulb close to the regulating bulb. The hunting was demonstrated by means of a platinum thermometer reading to 0·001° C. Other details of construction were explained. The same type of regulator is now being employed in experiments of the variation of the specific heat of water by a method in which two steady currents at different temperatures are allowed to mix, or share their heat, the resulting temperature being observed.

ALTERNATING-CURRENT MOTORS FOR ELEVATOR SERVICE.*

BY W. H. PATTERSON.

Squirrel-cage motors used for this service are designed with high resistance end rings, so as to develop maximum torque at starting. They will develop about twice full-load torque and take about 2·5 times full-load current when connected directly across the line. The control is by means of a simple reverse switch, thereby replacing the more expensive controller and rheostat required by a phase-wound motor. It is important that the torque be maximum at the start, for though the efficiency may be slightly improved by decreasing the rotor resistance, the motor would not then start at heavy loads. Moreover, as the required torque decreases after starting, an increased torque of the motor would cause a very sudden and disagreeable acceleration.

The best results are obtained when the slip is about 20 per cent. The full-load power factor was shown by the author to be about 80 per cent., and full-load efficiency about 70 per cent. While the apparent efficiency is low, it should not be compared with that of constant-speed motors, as in this service efficiency is unimportant compared with the other characteristics. The efficiency of the elevator machine itself approximates 50 per cent., and the power factor at starting varies from 70 to 80 per cent.

The wound rotor type machines have somewhat better starting conditions, developing twice full-load torque with about twice full-load current.

In discussing the conditions governing the size of motor required, it was shown that the nominal rating is of slight importance compared with the starting torque developed. The service conditions must then be considered to make sure that the operation is not continuous for long enough periods to cause overheating.

Squirrel-cage motors are made in sizes up to 18 H.P., this being the practical limit, due to starting current. They are used for freight elevators up to speeds of 100 ft. per minute, and in passenger service up to 150 ft. per minute. The wound secondary type is satisfactory for elevators of all capacities up to 250 ft. per min.

Elevators operating at higher speeds are practically always two-speed machines, a feature which eliminates the alternating-current motor, since with any given resistance in the rotor circuit the speed will vary with the load. Another feature limiting the use of alternating-current motors is the fact that with them dynamic braking can only be accomplished by the use of a small motor-generator set to supply direct-current excitation to the primary. However, alternating-current motors have been in use in elevator service for several years and have thoroughly demonstrated their adaptability for conditions within their range.

DISCUSSION.

Mr. F. E. TOWNE (Otis Elevator Co.) described the magnet control of slip-ring motors, and commented upon the difficulties in their application as compared with direct-current motors, particularly with regard to braking.

Mr. H. D. JAMES emphasised the importance of safety and reliability in this service, since failure might mean loss of life. This had probably retarded the development, because no changes which might possibly reduce the factor of safety could be tried.

Mr. J. E. MARTIN (Allegheny County Light Co.) presented some facts from the standpoint of the central station. He stated that the elevator load of a central station was generally confined to a district remote from other power loads, these same districts invariably having the most dense lighting load. In fact, the elevator load followed very closely the development of the lighting load and maintained a fixed ratio of about 11 per cent. of the total connected load. The load factor averaged about 40 per cent., as against 24 per cent. for lighting, and the demand factors had a smaller difference. The peak load on elevator installations occurred during the periods 7:30 a.m. to 8:15 a.m., 11:30 a.m. to 12:15 p.m 1 p.m. to 1:45 p.m., and 4:30 p.m. to 6 p.m. None of these peaks overlapped the lighting peak, excepting that occurring between 4:30 p.m. and 6 p.m. This showed that it was highly desirable to use one distribution system in the districts where the elevator load was found. The greatest disadvantage to be met in carrying out this principle was the intermittent nature of the load. On a circuit having an elevator load exclusively, the weight of copper had to be greater for a given load than for any other kind of service. It had been found advantageous and satisfactory to combine the elevator load with the lighting and a miscellaneous motor load if the elevator load did not exceed 5 per cent. of the total. This low limit was due to the heavy starting current and showed how important were the starting characteristics and how desirable it was to improve them.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough constant use, price 8s. 6d. post free. A complete Index is included.

SPECIAL NOTICE.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's cover. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

AUTOMATIC TELEPHONY.

The large audience which assembled at the Institution of Electrical Engineers last week was a testimony to the growing interest of English engineers in the subject of automatic telephony. Although in this country the authorities have not as yet seen their way to introduce what is known as the automatic system in any of the public exchanges, the development of the system in America and on the Continent has been considerable, and its introduction is said to have been attended with satisfactory results.

When a radical departure from ordinary practice, such as this system presents, is under consideration there are many weighty factors on both sides which demand careful and earnest study; the operating engineer who has to decide between the relative merits of the new system and the old has a very great responsibility, and his decision can only be arrived at after a long and patient investigation which will take into account the conditions at present obtaining and also the conditions which will exist some considerable number of years ahead.

The great innovation in automatic telephony is, of course, the abolition of the trained intelligence of the operator and the substitution therefor of a highly ingenious and compl

Digitized by Google

mechanism controlled by the untrained subscriber. It is around this point that much of the discussion centres, although, when carried to its logical conclusions, it embraces directly or indirectly the whole field of telephone engineering. In the manual system it has always been one aim of the engineer to reduce to a minimum the operations to be performed by the subscriber and, with a view to the reduction of maintenance expenditure, to make the subscriber's instrument as simple as possible. With the automatic system a comparatively complex instrument is used, and the operations to be performed by the subscriber are somewhat involved when compared with the simplicity attained on the other system.

As regards the exchange equipment, the automatic system has long since passed out of the experimental stage, and as it exists to-day is a remarkable testimony to the ingenuity and perseverance of the engineers responsible for its development. It can undoubtedly be relied upon to perform satisfactorily, to a very large extent, the functions of the human operator. There are, however, some operations which cannot be accomplished without the aid of human intelligence, and to carry out these successfully a certain number of human operators must be provided even in an automatic exchange.

A very important function of the operator who constitutes the human link in every connection on a manual system is not to be overlooked. No call can be completed without a preliminary conversation between the subscriber and the operator, with the result that every line is under the constant surveillance of an expert, and many incipient faults are thereby detected before the efficiency of the service is to any extent impaired. It is difficult to see in what manner a similar advantage can be obtained on the automatic system.

A comparatively large staff of highly-trained mechanics must be provided at the automatic exchange, and although the apparatus is so exceedingly ingenious and fascinating, it must not be overlooked that the maintenance charges on such a large amount of complicated mechanism as is found in an automatic exchange must of necessity be high. For similar reasons it seems inevitable that the depreciation charges also will be considerably higher than with the manual system.

A noteworthy aspect of automatic working is the fact that splitting up the system into a relatively large number of switching centres does not appreciably affect the service and does not increase the operating costs to anything like the same extent that a similar division would do on a manual system. As all calls are completed over junctions between the various groups of selectors it is to a large extent immaterial where these groups are located provided that undue costs are not thereby introduced. It is therefore possible to divide the subscribers up into geographical groups and to locate each of such groups from a small exchange located at the most economical point. By this means considerable economy in the plant can be made.

It is claimed for the automatic system that by its means the speed of the service is increased. If the time taken by the subscriber to operate the dial switch is not taken into account this claim can probably be justified. It must be remembered, however, that the automatic system does not eliminate any delays due to delinquencies of subscribers, and in a properly managed manual system whatever delays occur are due in a large measure to this cause rather than to any inherent delays in manual operating. A distinct advantage of the automatic system is the instantaneous disconnection of all the circuits concerned when the subscriber replaces his telephone, thereby leaving his line free for incoming calls in an appreciably shorter time than on the manual system. This has an important bearing in connection with junction working, since it results in the call-carrying capacity of a junction being increased.

The manual system as embodied in its modern form is the result of long years of development. It has proved itself in the past capable of meeting the continually growing demands of the telephone service, and in the opinion of some of the highest authorities it is well qualified to continue to do so in the future. Before abandoning such a system, engineers must satisfy themselves that in the automatic they have an alternative which will enable them to supply an equally efficient service at the same or a lower cost, and which will provide successfully for the ever-growing demands of a great public service.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Applied Mechanics for Engineers. By JOHN GRAHAM. (London: Edward Arnold.) Pp. viii. + 304. 5s. net.

The joint efforts of the author and publisher have resulted in the production of a very satisfactory book. The printing, illustrations and binding are well done, and the subject-matter, being in a style that is very readily followed, will be appreciated by all users. The author's course of lectures at the City and Guilds of London Finsbury College form the basis of the treatise. The elements of the subject are fully but concisely treated; the amount of descriptive matter respecting the practical application of the elements considered is wisely kept at a minimum.

Although it is unusual to introduce into a book on "Applied Mechanics" chapters dealing almost entirely with the expansion of steam in an engine cylinder, the author has seen fit to do so in this instance in order to lead up in a connected manner from the consideration of simple harmonic motion problems to the study of crank effort diagrams, and the balancing of machinery. A chapter on governors is also given.

The work on bending is treated in the usual text-book way—bending-moment diagrams considered without reference to the shearing force diagrams, and a few pages further on shearing force diagrams considered without reference to the preceding bending-moment diagrams. One objection to this method is that the student, not being shown at the commencement the close relationship between these diagrams, does not see any satisfactory reason for drawing a shearing force diagram; and further, when he does draw a shearing force diagram he finds that he has no apparent use for it. The Culmann polygon method of drawing bending-moment diagrams is too cumbersome to appeal to the designing engineer, and its very limited application does not warrant its having so prominent a place in text-books.

The earlier chapters naturally treat of the motion of matter and lead up to problems on energy and work. The three chapters on hydrostatics and the flow of water through pipes are well written. Graphic statics are treated fairly fully, and some consideration is given to braced girder work. A. C.

Elementary Telegraphy. By H. W. Pendry. (London, 1910: Whittaker & Co.) Pp. viii + 216. 2s. 6d. net.

This book is written specially to meet the requirements of the ordinary grade of the subject as published in the syllabus of the City and Guilds of London Institute. The author claims that a first text-book of this sort has been long wanted, and in this he is no doubt correct. To a great extent the order in the syllabus has been followed, this being most convenient to the candidates for examination. A number of questions are appended to each chapter, which are partly original and partly selections from recent examination papers. The author recommends the student to work these exercises systematically, and the careful preparation of the questions would seem to render this advice valuable. There are 200 illustrations in the book, which help to give the student clear ideas of the forms of instruments used in telegraphy, and of the mode in which they are connected up. The mathematical expressions which are employed do not go beyond simple equations, and, so far as they go, are thoroughly in keeping with the rest of the descriptive matter.

Chapter I. deals with fundamental principles, units, the phenomena observed when we come to work with electro-magnets, and the construction of bobbins. Batteries of the popular forms—the Daniell, the Leclanché, the bichromate, dry, and secondary cells are well described in Chapter II. Appropriately, the reader is then introduced, in Chapter III., to the instruments in common use for simplex and duplex working, together with the forms of galvanometers, with their shunts, which are ordinarily employed in England. Switches, resistance coils and condensers as used in the British Post Office are included. Within a short compass there are set out, in Chapter IV., the main features of construction of aerial, subterranean and submarine lines. A full-sized section of a composite telegraph and telephone air space cable, and another of a Continental quad gutta-percha cable, are illustrated and instructively described. Chapter V. deals with signalling systems, including duplex, C.B. arrangements, condenser, impulse, and omnibus circuits, the Hay and Vyle and Smart duplex, and special Wheatstone and key circuits. The mode of using and of connecting up to distribution, main cabinet and table fuse cases, and the universal battery are also treated. Chapter VI. contains descriptions of modern methods of prevention of disturbance by earth currents and lightning. This is followed by an appendix giving questions set at the City and Guilds Institute in 1908–10. A useful index concludes the book. The work is a good one and deserves to be largely used, for it contains all the information likely to be required by the elementary student presented in a well-condensed and able manner.

Annuaire pour l'An 1911 du Bureau des Longitudes. (Paris: Gauthier-Villars.) Pp. 640 with Appendixes. 1 fr. 50 c.

This annual contains, firstly, details which are likely to be of interest to astronomers. This part comprises constants, data and information, in the usual pocket-book style, regarding the sun, the moon and other heavenly bodies. The second part contains tables giving geographical data of the principal countries, together with the latitude, longitude and population of the chief towns and cities. Conversion tables for the money, weights and measures of the various countries are also given. The information seems to have been adequately brought up to date since the last issue, though the volume is about 100 pages smaller. This decrease is due apparently to the fact that no dissertation on a special subject is included. Unlike most French books of its kind, this annual possesses quite an adequate index.

Spon's Architect's and Builder's Pocket Book. (London: E. & F. N. Spon.) Memoranda Section, pp. liii. + 372, 2s. 6d. net, post free. Prices Section, pp. liii. + 239, 2s. 6d. net, post free.

Since the last edition it has become necessary, owing to the inclusion of new matter and the consequent increase of the thickness of the volume beyond pocket-book size, to divide the Memoranda from the Prices section. In the first of these the memoranda are arranged in alphabetical order, and all the information has been brought up to date. The subjects covered are exceedingly varied, the range being comparable with that of "all Lombard-street to a China orange." As regards electrical work, nearly 30 pages are devoted to the question of lighting by this means. Some useful figures are given regarding the amount of light that should be used for illuminating various areas. A model specification for a self-contained lighting plant is given in full, as well as extracts from the wiring rules of the Institution of Electrical Engineers. The section gives a number of prices for doing work in the building trade, the standard taken being for operations of average size, carried out under the ordinary conditions in the London district and including profit. Electrical work figures in this section as well, the cost of wiring and fitting electric light when casing or tubing is employed being given.

L'Année Electrique, Electrothérapique et Radiographique. By Dr. Foveau de Courmelles. (Paris, 1911: Libraire Polytechnique Ch. Béranger.) Pp. 348. Fr. 3.50.

This edition varies but little from its predecessors. In specially written chapters an adequate *résumé* is given of the progress made during 1910 in apparatus, heating, electric traction, wireless telegraphy, hygiene and medical electricity. We imagine that this book is written for such medical men as desire to know a little of what is going on outside their own sphere of usefulness. For this reason we think an index might have been provided. We have drawn attention to this point before, but it is a defect often found in French books.

THE NOMENCLATURE OF PRIMARY AND SECONDARY SOURCES OF LIGHT.

BY HAYDN T. HARRISON.

The short Paper I read before the Illuminating Engineering Society has already justified itself by producing from Mr. Trotter one of the most valuable articles (The Electrician, May 19th, p. 204) on the subject of the terms used in optical science. But it will be noted that those terms which have been already defined do not include one which is badly needed—namely, that which will differentiate between illumination derived from light radiated from a point and illumination reflected from a large area.

In order that the necessity for such a term may be made clear I will take a simple example. Let us suppose a room in which the walls, ceiling and floor all have a high reflecting efficiency. In the centre of that room is placed a single light source, and below this, but protected from the direct rays, is some object such as a small sphere. Now, to the human vision that sphere will not appear spherical, however highly it is illuminated, because the illumination is derived equally from all directions. In other words, the illumination might be good as far as degree is concerned, but would be a failure as far as seeing solid objects is concerned.

Illumination, as defined by the terms at our disposal, does not differentiate between the class of illumination which makes visible the details of solid objects and that which will not. Illumination is the quantity and quality which stimulates the eye in discrimination of outlines and perception of colours; then in order that we may know the extent to which it is likely to assist us in the discrimination of outlines, it is necessary to know the area of the source from which the light emanates and also the direction. A monochromatic solid object, like statuary for instance, demands that every curve or angle must reflect varying degrees of light back to the eye in order that it can be seen in detail, and this applies in varying degree to all objects except plain artificial ones, such as pictures, where the artist has done what the varying degree of illumination has to do in the case of a solid object. Therefore, if an illuminating engineer specifies only the degree of illumination in foot

Digitized by Google

candles, or any of the other terms at present in use, he must not be surprised if the result is not satisfactory.

Having found this difficulty, I sought for some term that would distinguish between the rays from light sources which produce the effect of light and shade and those which do not. The latter were described in my Paper as the cause of shadowless illumination.

It is obvious that in cases where the light is radiated from one or more sources the effect of light and shade will be produced, whereas if it emanates from all directions, being reflected by the luminosity of the surrounding surfaces, the opposite effect will be the result. Therefore, if the term luminosity is to be used to indicate the reflecting value of these surfaces, I suggested that Lumens should be allotted to light flux obtained by reflection. The objection to this appears to be that the term "Lumens" has already been appropriated. Therefore it would perhaps be advisable to coin a new term for the light-emitting power of a secondary source, and a new unit to describe the value of the illumination derived.

This is not the first time a problem of this sort has had to be faced. For instance, the electrical law W = E.C., which Varley and Tait have both pointed out, bears a remarkable resemblance to the law of lighting, is not correct when applied to alternating current passing through an inductive circuit; hence the word "true-watts" has often to be used. In the same way the physical value of illumination is not always equal to surface radiation per square centimetre multiplied by the area of the light source. Therefore, the unit required is that which distinguishes between the light flux which produces contrasts and that which does not. It would then be possible to judge the true physical value of the resulting illumination.

All illumination derived from a source of comparatively small area will accentuate contrasts of light and shade, and that derived from a relatively large area will reduce them. So, mathematically, the unit is required to describe the degree of divergence from the $i = \frac{CP}{D^2}$ formula, where candle-power is taken as emanating from a point source; in other words, a factor which reaches unity when illumination is derived equally from all directions, and a maximum when illumination is derived from one infinitely small point.

There should be no difficulty in giving this unit a mathematical value. For example, if a lamp gives 0·01 ft.-candles at a distance of 10 ft., it will give x foot-candles measured at 1 ft. from an albedo plain surface of practically infinite area illuminated by a 1 c.p. lamp at a distance of 5 ft. Thus the new unit would denote a shadow-giving efficiency of $\frac{0{\cdot}01}{x}$, and could be measured by an ordinary illumination photometer by measuring the illumination on the bright and dark side of an object. The difference would give the relative shadow value of direct and indirect lighting, which would be the maximum if all the lighting were obtained from a point source, and a minimum when the light is obtained equally from all directions.

I trust the readers of this will agree with me as to the need for a new unit to denote light and shade efficiency, as, until some suitable term is forthcoming, it will have to be described as a shadow efficiency or similarly ambiguous phrase.

It is interesting to note that in daylight the shadow efficiency is greatest with bright sunlight and lowest when the sky is overcast, thus emphasising my point that if a lesson is to be learnt from Nature, the most unpleasant illumination is of the shadowless type, or when the illumination derived has a very low shadow efficiency.

It must not be gathered from these remarks that I consider heavy shadows an essential for good illumination, but that I consider the presence of shadows produces an efficient illumination physiologically. Certain conditions require different degrees of light and shade, and the best effect for each class could be ascertained by experiment and properly specified, provided there was a unit or standard by which to specify them.

THE HEATING OF CABLES WITH CURRENT.*

BY S. W. MELSOM AND H. C. BOOTH.

Summary.—Investigations on the rise in temperature of various sizes of conductors carrying current are discussed, the effect of stranding, of installing in tubes, wood casing, &c., and of various methods of insulating and covering being described. The results of this research are incorporated in the recently issued sixth edition of the Wiring Rules of the Institution.

This Paper describes an investigation made at the National Physical Laboratory at the request of the Wiring Rules Committee of this Institution in order to determine the temperature rise and current-density for a given temperature rise in cables of various sizes and with different types of covering. A length of 40 ft. of each cable was tested. The insulation of the cables was of the standard pattern, the paper-insulated ones being lead covered, and the rubber-insulated (with the exception of the 0·3 sq. in., which was only rubber covered and taped) being taped, braided and compounded.

Conditions under which Tests were Made.—The rubber-covered cables, marked A on the curves, and the paper-insulated lead-covered cables, marked E on the curves, were in each case laid out flat along the wooden floor of the room, the lead and return being close to and touching each other. The concentric paper-insulated lead-covered cables (F_1 on the curves) were laid straight out along the floor, the current being led into the inner and returning by the outer lead.

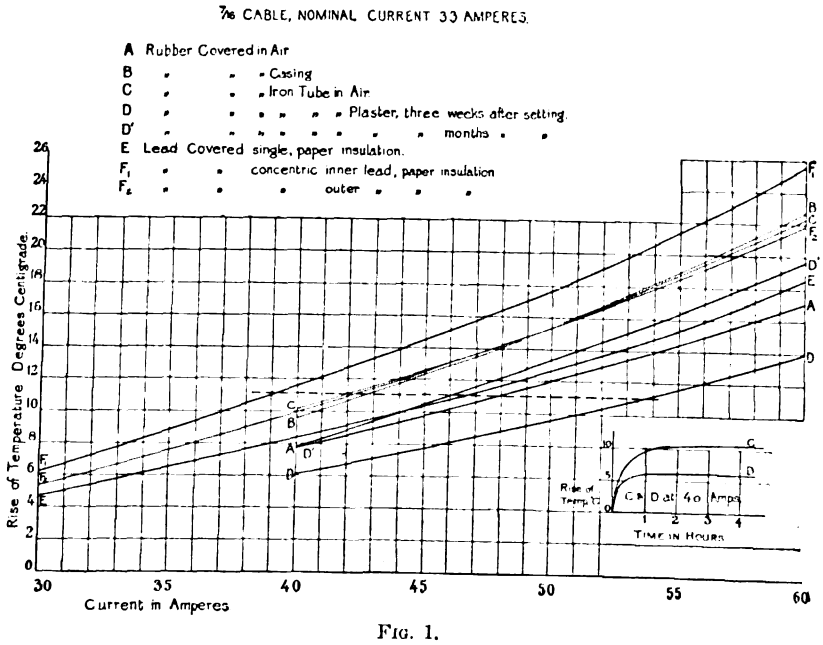

FIG. 1.

In the case of the rubber-covered cables in casing, marked B on the curves, the casing used was in each case twin and of the standard size for the various cables, and was supplied by the Wiring Rules Committee. The casing, however, in some cases allowed of a rather larger air space than in others. The ideal condition from the point of view of dissipation of heat is to have the cable nicely filling the groove. The casing was laid flat along the floor. Observations made with it screwed to a board and supported on one edge, with the wires one above the other, showed no difference whatever from those made with the casing laid flat and with both wires in the same horizontal plane.

The iron tubes used were supplied by the Committee. In each case both the lead and return cables were drawn into the same tube; and as there was a considerable amount of air space inside the tubes, this would tend to retard the dissipation of heat. The cables marked C on the curves were drawn into the iron tubes and laid straight out along the floor. In the case of those marked D and D' the tube was embedded in a block of plaster running the whole length of the tubes, the plaster being 4 in. deep by 6½ in. wide.

* Abstract of a Paper read before the Institution of Electrical Engineers.

Digitized by Google

Measurement of Temperature Rise.—The increase of temperature of the cables was determined by measuring the increase of conductor resistance. The initial temperature of the cable was assumed to be that of the air. Observations taken both on a rising and falling air temperature showed that even the larger cables followed the slow variations of air temperature very well. The room in which the tests were made was specially adapted for constancy of temperature and was free from any draught.

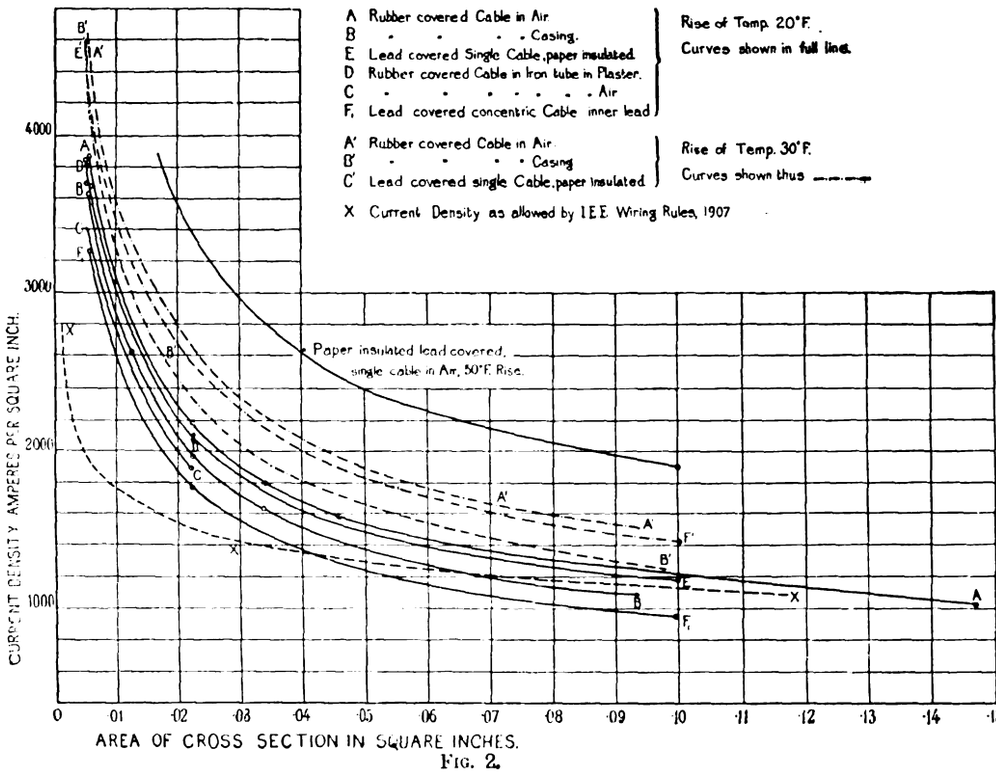

FIG. 2.

An interesting point was raised by Mr. Wordingham in connection with this method of determining the temperature rise. It was that there was a possibility of the strands of the larger cables when hot coming into better contact than when cold, and that, consequently, the resistance of the conductor would not rise proportionately with the temperature. This point was investigated by enclosing the 0·5 sq. in. paper-insulated lead-covered cable in a long wooden box, which was heated by means of woven resistances to a temperature of 50° C. As the temperature coefficient of the conductor was thus found to be 0·396 per cent. per degree Centigrade, as against 0·40 per cent. obtained by the more accurate method of measuring the separate wires in an oil bath, the variation in resistance, if any, due to tightening of the strands does not affect the accuracy of the results. The temperature determined throughout the tests is, of course, the mean temperature of the conductor over its cross-section, and not the maximum to which any part may have risen. Dr. A. Russell has stated that the temperature difference is very small.

In order to ensure that there was no extraneous heating or cooling at the ends, the connections from the cable to the standard resistance were made with cable having the same cross-section as that under tests, the joints were wrapped with canvas wrapping and the potential leads from the cable to the bridge were taken off at a point just inside the joints.

The current was taken from a large battery and was kept quite steady throughout the tests.

In order to ascertain if there was any large difference between the heating with direct and alternating current, a test was made with the paper-insulated lead-covered cable and the rubber cable 0·5 sq. in. section with alternating current of 50 cycles per second. The cable was heated by means of alternating current, the measurement of resistance being made by changing over to direct current immediately before the observation was made. The results agreed with those obtained with direct current to within about 3 per cent., this being within the probable limit to which the alternating current was kept constant.

Results.—Three small cables (1/14, 3/18 and 7/21) were first tested to ascertain the difference between stranded and single conductors. In order to make a correct comparison, the results were corrected for the small differences in cross-section between the conductors. It was found that the difference in the current required for a given temperature rise was only 3 per cent. between 1/14 and 7/21 cable, the actual temperature difference being only 1°F. with a current of 20 amperes.

Fig. 1 is typical of the results obtained with different types of covering for a 7/16 cable. In general, the current-carrying capacity of rubber cables for a temperature rise of 20°F. is about 10 per cent. less when they are run in casing than when they are laid out along the floor—*i.e.*, in air (the latter, of course, approximates to the conditions of cables cleated to a wall or in a wood chase). There is also very little difference between the rubber and paper-insulated cables when laid under similar conditions. It is, perhaps, interesting to note that the difference between rubber cable in casing and in iron tube in air (*i.e.*, laid along the floor) is very small. When, however, the iron tube is embedded in plaster the cooling is distinctly better, the curve being nearly the same as that obtained with the lead-covered single cable.

Figs. 2 and 3 show the results for the whole series of cables tested in current-density per square inch of conductor for a given temperature rise. Each of the cables examined was run with a steady current until a final maximum rise of temperature above that of the surrounding air was attained, the time ranging from two up to five or six hours.

For each type of cable and each condition of running a curve was drawn, showing, for a specified final temperature rise, the connection between the cross-sectional area S and the current-density *i*. It was found that in certain cases—*i.e.*, single rubber-covered cables in air and in wood casing and paper-insulated lead-covered cables, both single and concentric—the connection between cross-section and

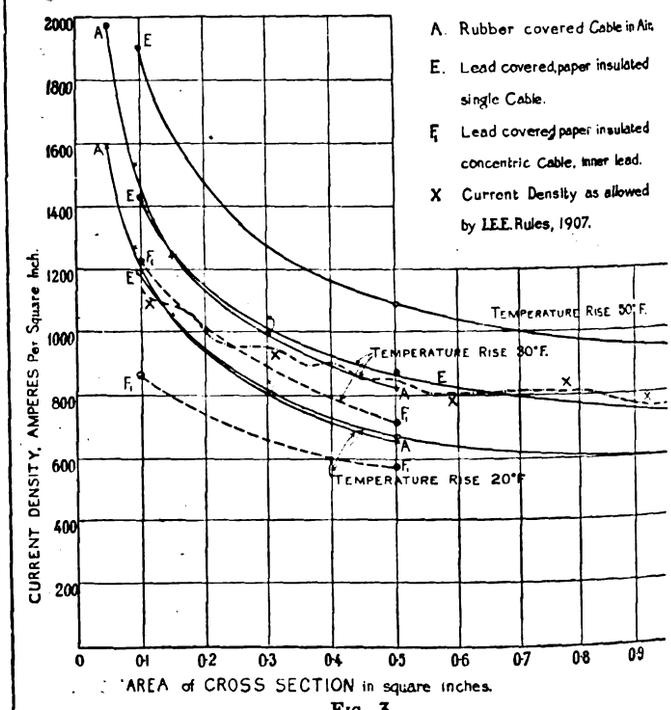

FIG. 3.

current-density could be fairly represented by a formula of the type $i = K(D/S)^n$, where n is a constant and K depends on the system of units adopted and the amount of the temperature rise. If i is the current-density in amperes per square inch, S the cross-section of the copper in square inches, and D the diameter of the outside covering

Digitized by Google

the cables in inches, then, for a rubber-covered cable in air, $i = 364\,(D/S)^{0.461}$; for similar conductor in casing $i = 309\,(D/S)^{0.66}$, and for a lead-covered cable, $i = 429\,(D/S)^{0.5}$, the temperature rise assumed in each case being 20°F. For a 30°F. rise K is 457, 358 and 336 respectively for the above three types, n being unchanged. For a 30°F. rise K = 688 for a lead-covered cable.

The authors next explain the reasons which suggested the use of this particular type of formula, this being obtained and the various constants discussed.

CURVES SHOWING HEATING OF 19/14s CABLE LAID UNDER VARIOUS CONDITIONS.

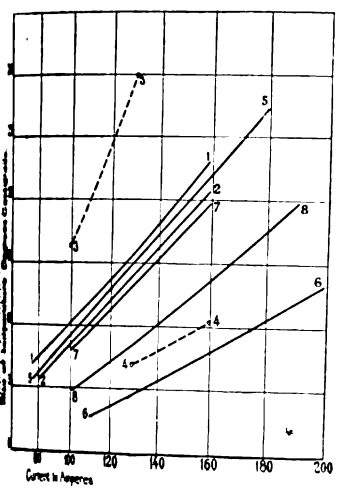

FIG. 4.

The dotted curves marked X in Figs. 2 and 3 give the current-density allowed by the present (1907) Wiring Rules. It will be seen that this gives a temperature rise of about 20°F. for cables of from 0·046 sq. in. to 0·15 sq. in., rising to rather more than 30°F. for cables up to 1 sq. in. section. For cables smaller than 0·05 sq. in. the temperature rise with the current-density at present allowed is much less than 20°F.

Tests under Extreme Conditions.—In Fig. 4 are shown results obtained with 19/14 cable laid under various conditions.

The question of the heating of buried cables is a most important one. It has been somewhat outside the scope of the present work, however. So far as the authors are aware, no attempt has been made by the engineers responsible for large cable systems to determine the temperature rise in the cables as laid. It would not be very difficult to obtain data of this sort, which would be extremely valuable. A test of the voltage drop along a length of cable from the distributing station to the first distributing box at various currents or conditions of loading could be easily made. It would, however, probably be insufficient to take the total volts at each end of the cable, as the difference would be so small, but if a small wire were run back along the cable the voltage drop could be taken sufficiently accurately on a low-reading voltmeter.

Intermittent Load Tests.—The extent to which the nominal rating of cables might be modified where the load is intermittent in character was also investigated. The authors of the present Paper took a period of four-minutes' running, followed by six-minutes' rest, and, as a variation of this, a period of two-minutes' running followed by three-minutes' rest; and in each case measured the rise and fall of temperature going on in the cable under these conditions of working. A 19/14 rubber-covered cable, the nominal rating of which under the new rules is 119 amperes, was chosen for the test, and was run at 50 per cent. overload. The results show that in the shorter period the maximum peak of the temperature curve just reaches the 20°F. limit. In the case of the longer period that limit is slightly exceeded.

CORRESPONDENCE.

THE ORIGIN OF "ATMOSPHERICS" IN WIRELESS TELEGRAPHY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As Dr. Erskine-Murray now proposes to use directive aerials for his investigations on the origin of "atmospherics," it may be of interest to state that in the early days of directive aerials (1907) it was noticed by the writer, and also by Messrs. Bellini and Tosi, at the Dieppe station, which was fitted with a directive system, that such atmospherics as were received on the directive receiver were by no means uniformly distributed in azimuth; and though the idea of using these aerials for this purpose has only lately suggested itself to radio-telegraphists, meteorologists were quick to see the important information which directive aerials might give them. In the latter part of 1908 a Bellini-Tosi directive receiving aerial with radiogoniometer was installed at the Meteorological Observatory at Antananarivo, in Madagascar, in order that observations of atmospheric discharges could be carried out, and, as this was over two years ago, it would appear that a considerable fund of information should already be available, especially as the station is situated where there should be abundant material for observation.—I am, &c.,

London, W.C., May 22. L. H. WALTER.

NEW DEMONSTRATION ROOMS OF THE WESTMINSTER ELECTRIC SUPPLY CORPORATION.

Further evidence of the publicity campaign which has been organised by the electric supply companies of London was the opening on Wednesday last of the new demonstration rooms of the Westminster Electric Supply Corpn. at their main offices in Eccleston-place, Belgravia, S.W. This Company has for some years demonstrated on a small scale the capabilities of electric lighting and electric appliances, but the extensive and exceptionally well equipped new demonstration rooms should enable the Company to develop the publicity side of their undertaking in a more effective manner. The equipment and arrangement of the rooms certainly leave little to be desired, and visitors cannot fail to be impressed both by the attractive display of apparatus and by the demonstrations of its capabilities.

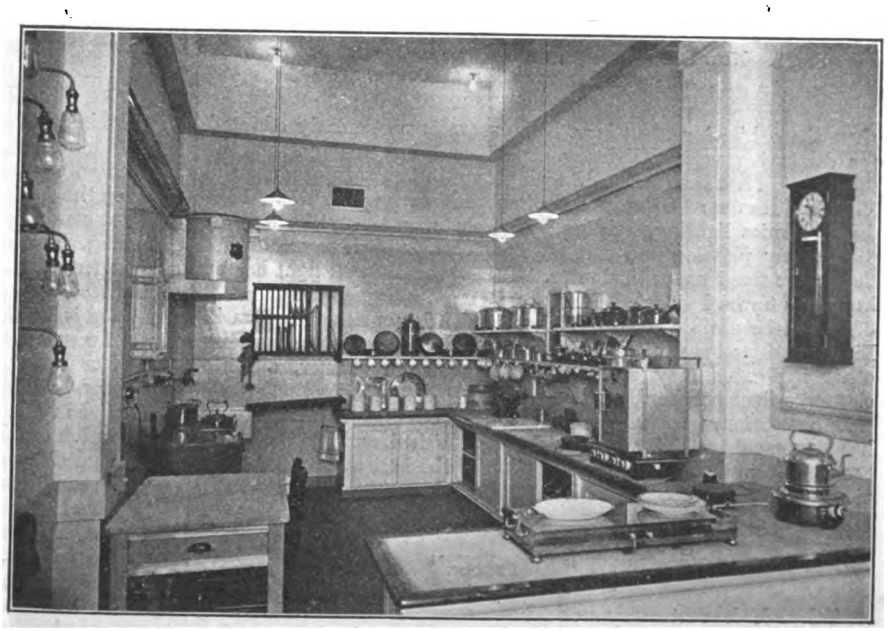

FIG. 1.—MODEL ELECTRIC KITCHEN IN THE NEW DEMONSTRATION ROOMS OF THE WESTMINSTER ELECTRIC SUPPLY CORPN.

Digitized by Google

In this connection the greatest credit is due to the Company for the effort which they are making to popularise the use of electrical energy for purposes other than lighting. A model kitchen is included in a bay of the main room, and in addition to the demonstrations which will be given of the use of various electric-cooking utensils, ladies will be invited to send their cooks to the Company's rooms to investigate and obtain experience in the actual use of electrical apparatus. Moreover, the attendant will visit consumers' houses to instruct and advise on the use of electric-cooking apparatus, so that consumers are not likely to refrain from adopting electric cooking on account of ignorance of its possibilities. As regards cost, the Company are satisfied that electric cooking with energy at 1d. per unit is no more expensive than gas at 2s. per 1,000 cubic feet.

We noticed in the model kitchen, of which a view is given in Fig. 1, that a constant supply of electrically heated water is obtained from a "Therol" water heater. A "Tricity" cooker is also much in evidence, and visitors to the rooms on Wednesday last were able to sample a number of foods cooked in this oven, verifying for themselves the statement that electrically cooked food surpasses in flavour that cooked by ordinary methods.

As regards the main showroom, of which a view is given in Fig. 2 herewith, the Company has had more especially in view the practical application of the various systems that may be employed, rather than the exhibiting of fittings. The room is particularly adapted for displaying various lighting effects, and for this purpose the illumination has been arranged with groups of lamps to produce the following results: Upward reflection, downward reflection, concealed cornice lighting, lighting by brackets on the walls, &c. A particularly pleasing and soft effect is obtained where white silk shades are fixed under the lamps. This gives diffused light below, as well as upward reflected light.

As will be noticed from the view of the demonstration room in Fig. 2, various types of electric radiators are shown, whilst among other apparatus may be mentioned a vacuum cleaner, a knife cleaner, a floor polisher, flat irons, &c.

In conclusion, we need scarcely add that the demonstration room has been most tastefully decorated and furnished, and the Company are to be congratulated on what is one of the best arranged exhibitions of electric apparatus we have seen.

FIG. 2.—NEW DEMONSTRATION ROOM AT THE OFFICES OF THE WESTMINSTER ELECTRIC SUPPLY CORPN.

THE "AMPALL."

Although the customary method of measuring the current flowing in a conductor is to include an ammeter in the circuit, cases frequently arise where it is inconvenient or impossible to break the circuit for the purpose of inserting an ammeter. The Ampall, a new instrument which has just been placed on the market by Mr. R. W. Paul, of Newton Avenue Works, New Southgate, N., enables the amount of current to be ascertained without breaking the circuit.

The apparatus, which is illustrated in Fig. 1 herewith, comprises a "Unipivot" millivoltmeter, a contact block with potential points and plug leads. The contact block is strapped by leather bands to the bare conductor in which it is desired to determine the current flowing, the plug leads are connected up and the reading of the millivoltmeter noted; this reading multiplied by the cross-section of the conductor in square inches gives the value of the current in amperes. In order that this may result, the millivoltmeter scale is arranged so that it reads 1,000 when the difference in potential between the contact points is 2 millivolts; and the distance between the contact points on the block strapped to the conductor is arranged so that there is a P.D. of 2 millivolts when the conductor is carrying 1,000 amperes per square inch. This distance is approximately $2\frac{3}{4}$ in.

It will be seen, therefore, that the millivoltmeter reading gives the current density in the conductor; and the product of this reading and the area of the conductor furnishes the required value of the current flowing. An important feature of the instrument is that it enables the amount of current from a fraction of an ampere up to any value to be ascertained, and there is always an open reading on the scale. The method of using the apparatus and of fixing the contact block will be clear from Fig. 2, which illustrates the Ampall in use for reading the current in a copper battery connection. It must be noted

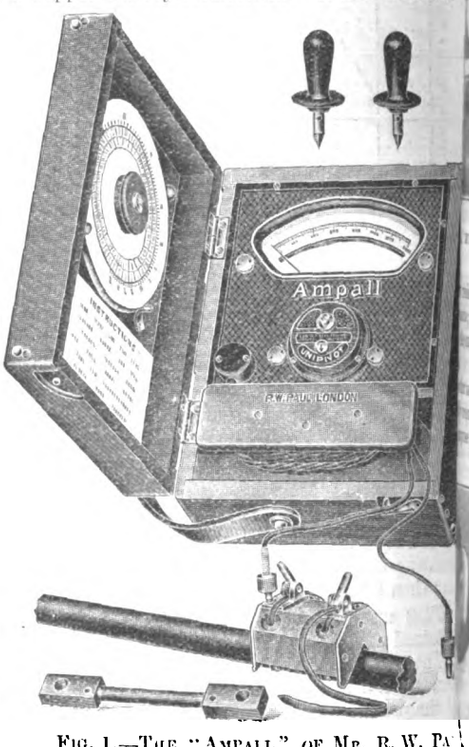

FIG. 1.—THE "AMPALL" OF MR. R. W. PA

that the instrument is calibrated for copper conductors, so that wit conductors of other metals, the reading must be multiplied by th percentage conductivity and divided by 100, or else the distanc between the contacts must be correspondingly altered. In the cas of a flat conductor, or one of irregular shape, no difficulty arises attaching the contact block, which is arranged so that it press against the surface. We may mention that the apparatus has r cently been employed successfully for conductors measuring 5 in. b 2 in., and it should prove valuable for measuring currents in variou parts of power or lighting systems, and in connection with electrolyt or furnace work. A simple circular slide rule is also provided; this graduated both in square inches and in sizes of stranded cables, an enables the value of the current to be read off quickly.

Attention must, however, be called to the fact that the Ampall not intended for use as a precision instrument, but in unskilled hand readings can be ascertained within a few per cent. Exact results ca be obtained in skilled hands if due regard be paid to the conditions the test. Thus, the instrument does not compensate for the rise temperature of the copper conductor under test. As, however, rise in temperature of 20° F. covers the majority of cases, the distan apart of the contacts has been fixed on the assumption of a temper ture rise of 10°F. (the actual distance apart of the contacts is 2·87 in

In addition to its use for measuring current the Ampall provides simple means of testing the conductivities of contacts, joints, fuse or materials generally. For this purpose hardened steel points (se at the top of Fig. 1) and a copper resistance (seen in the foregrou of Fig. 1) of 20 microhms for use as a standard are included. T standard 20-microhm resistance requires to be inserted in the circu By taking readings on the millivoltmeter of the P.D. across this res tance and across the contact or bar to be measured, the conductivi

Digitized by Google

can be at once obtained. Where it is possible to adjust the current, the procedure can be simplified by adjusting the current so that a reading of 200 is obtained on the millivoltmeter across the 20 microhm resistance. The unknown resistance in microhms is then obtained by dividing the reading by 10. The apparatus is seen in Fig. 3 in use for testing the conductivity of a carbon rod. An exten-

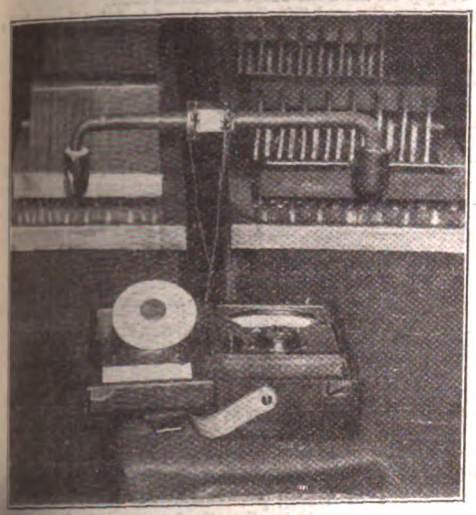

Fig. 2.—The "Ampall" in use for Reading the Currents in a Battery.

sion piece of 90-ohms resistance is also provided, and can be easily fixed to the plug contacts; as the resistance of the millivoltmeter is 10 ohms, the use of the extension piece results in the scale reading directly in microhms.

As illustrating a further use of the Ampall, we may mention a case where it is occasionally required to read the current in a number of circuits. For this purpose it is not necessary to fix ammeters

Fig. 3.—Testing the Conductivity of a Carbon Rod.

or shunts in each circuit, but a contact block would be tied to any part of each circuit and leads brought to the contacts of a multiple-way switch; the contact blocks being adjusted to suitable lengths, direct readings in amperes are obtained on an "edgewise" Unipivot instrument.

THE "CARLEON" SYSTEM OF LIGHTING FOR MOTOR CARS.

During the last year or two considerable attention has been paid to the problem of providing a satisfactory system of electric lighting for motor cars. The difficulties to be overcome in evolving such a system are many, among them being that of obtaining a practically constant voltage at varying speeds of the engine, and of ensuring that the battery shall not be subjected either to insufficient or unduly heavy charging.

One of the most interesting systems that we have seen is known as the "Carleon." This is due to Mr. Gavan Inrig, of Medina Works, Kew Green, S.W., and brief mention of it was made in our "Industrial Supplement" of Feb. 17 last, though, unfortunately, the name of the inventor was incorrectly stated as Turig. Mr. Inrig has been engaged on the problem of car lighting for many years, and produced a special dynamo for this purpose as early as 1898. The present "Carleon" generator is constructed on different lines from those usually followed, the voltage of the machine being maintained constant over a wide range of speed by varying the air-gap between the armature and the field magnets.

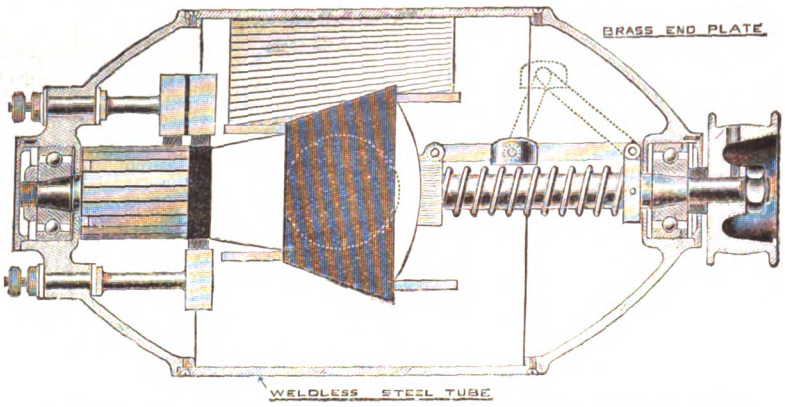

Fig 1.—Diagram Illustrating Principle of "Carleon" Generator

As will be seen from Fig. 1, the armature is cone shaped, and its position relative to the field magnets is adjusted by a centrifugal governor. The total travel of the armature is 1½ in., and in its limiting position each air-gap is ⅜ in. This position, however, is not likely to be reached, since at 4,000 revs. per min., the armature is only displaced 1 in. The lower limit at which the armature supplies current to the lamps or battery is 1,400 revs. per min.

The generator, of which a view of an early type is given in Fig. 2, is a four-pole shunt machine, and four brushes are used to collect the current from the commutator. Two additional brushes are attached to the end of the spindle and are displaced radially by centrifugal force when the armature is rotating, their position being controlled by two springs. Each of these brushes, which are not indicated in the diagrammatic representation of the generator in Fig. 1, and which are insulated from one another, comes into contact with at speeds above 1,400 revs. per min. and short-circuits two insulated brass rings fixed inside the generator casing. This serves

Fig. 2.—Early Type of "Carleon" Generator.

to connect the armature to the main terminals of the machine when the normal voltage is reached, so that a switch is unnecessary. The maximum output of the machine is 10 amperes at 15 volts, but a smaller generator is being put on the market to meet the requirements of taxicabs. The larger generator weighs 21 lb.; its overall length is 8½ in. and its diameter 6 in.

The battery is connected permanently to the terminals of the machine, so that charging takes place whenever the generator runs at a higher speed than 1,400 revs. per min., the pressure being 14 - 15 volts. The storage battery marks a new departure in the construction of accumulators, neither lead nor acid being employed. One set of plates consists of zinc and the other of a star-shaped carbon rod embedded in a block containing manganese peroxide, graphite, zinc chloride and sal ammoniac. These ingredients in certain proportions are made into a paste with distilled water and pressed into a block containing the star-shaped carbon at the centre. The electrolyte comprises crushed oats, crushed rice, zinc chloride and sal ammoniac. The cell is therefore of the dry cell Leclanché type.

Ten cells are employed and the advantages claimed for the battery

Digitized by Google

are that there is no paste to fall out and make short-circuits, no acid or fumes, so that the terminals cannot be corroded, its weight is 50 per cent. less than that of lead accumulators, it requires no attention and is absolutely fool-proof. In this last-mentioned connection it is interesting to note that the battery is claimed to be in no way injured by heavy charging currents. Thus, a current of 30 amperes has been found to cause no harmful results. In other respects the battery, which is at present being manufactured in the 40-ampere-hour size, is charged and discharged in the usual manner. A disadvantage is that during normal discharge its voltage decreases from 1·5 to 0·9 volts, so that when the speed of the engine falls below the minimum for charging, a decided diminution in light is obtained on the lamps. As a good light is usually of particular importance when bringing a car to rest rapidly this feature must be off-set against the disadvantages of lead accumulators. The latter can, however, be employed with the "Carleon" generator if desired. The weight of the 40 ampere-hour battery mentioned is 26 lb., and its dimensions are 16 in. long, 7 in. wide, and 7¾ in. high.

Attention may also be called to the "Carleon" motor lamps. Fig. 3 shows a sectional view of one of these. A special feature is

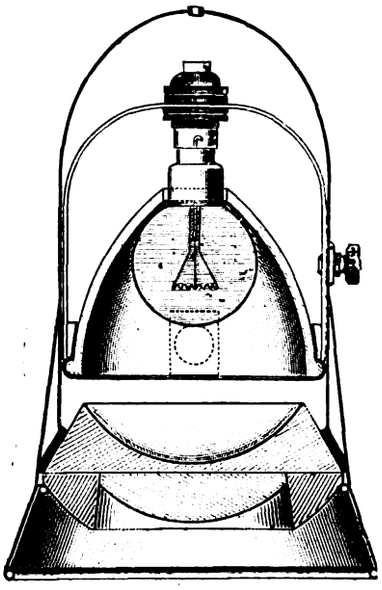

FIG. 3.—"CARLEON LAMP."

the reflecting hyperbolic mirror, made of double glass, silvered between. By this method of construction, the brightness of the reflectors remains unimpaired. The light passes through a concave lens and is projected through an annular dioptric lens in a parallel beam of light straight in front of the car. It is claimed that all glare and dazzle has been eliminated by this arrangement of lenses. It is interesting to notice that no special shape of lamp bulb is necessary, it being possible to employ any bulb up to 2 in. diameter.

Electric Traction in Switzerland.—Some weeks ago we announced that the Swiss railway authorities were taking steps for an extensive electrification of their lines. We understand from "The Times Engineering Supplement" that the authorities have already acquired several concessions for water power in the region of the Simplon, in the cantons of Uri and Ticino, and elsewhere; and now they have just concluded an agreement with the authorities of the canton Valais. By this agreement they obtain the right to utilise the power of the waters of the Rhône between Fiesch and Mörel, where electricity works are to be built. On the Gothard line about 10 miles of water conduits have been built between Arolla and Bellinzona, preparatory to the electrification of this line from Lucerne to Chiasso. It is calculated that between 25,000 and 30,000 H.P. will be obtainable from these works alone. The concessions for utilising the water power on both sides of the Gothard Pass, in the cantons of Uri and Ticino, have also been secured. The electrification of the railways will naturally entail a heavy initial cost, the price paid for the concession in the Rhone Valley alone having been £15,200, besides an annual payment of £1,600. It is estimated that when the Valais works are ready the *minimum* yield of power will be 15,500 H.P.

PARLIAMENTARY INTELLIGENCE.

POST OFFICE ESTIMATES.

On Thursday evening last week the House of Commons went into Committee of Supply on the Post Office Estimates, when

The Postmaster-General (Mr. SAMUEL) explained that the vote for the year (amounting to over £21,000,000) exceeded that for last year by £1,750,000, due mainly to the taking over by the Post Office in January next of the business of the National Telephone Co.; £480,000 was required for the first quarter's working expenses and £131,000 in connection with the inventory and for rearrangements of telephone equipment, the total amount in respect of the transfer of the Company being £798,000. The balance of the increased expenditure was due to normal growth of Post Office work (£343,000), to telephone repayment charges, provision of a new cable ship, &c. The estimated revenue was £25,740,000, increase £2,000,000. The estimated Post Office profit for the year would be £4,615,000, increase £666,000.

Postal Reforms.

Mr. Samuel announced that he proposed on Coronation Day to issue postcards and letter-cards at ½d. and 1d. respectively, that was, at the face value of the stamps upon them. The actual cost of the postcard to the Post Office would be ⅓d., and it was impossible to defend the present charge of a farthing. A satisfactory margin of profit would still remain. He proposed to make two alterations so as to meet objections of the stationery trade. He saw no reason why the Post Office should supply postcards at the face value and give wholesale firms special facilities for obtaining their stationery for nothing, and he had made arrangements to discontinue the practice of selling postcards in uncut sheets. And, further he had made arrangements to allow the free stamping of official stamps upon any postcards privately manufactured and presented for stamping. He also proposed to sell 2s. worth of stamps for 2s. in the little book hitherto containing only 1s. 11½d. worth of stamps. Also on Coronation Day the public would be able to obtain most of the stamps of the new issue bearing the image of King George. He proposed to improve the perforation of stamps and letter-cards, and after the new issue had been made he would place on sale postage stamps in the form of rolls as well as sheets. In consequence of representations from Chambers of Commerce and the trade there would also be provided in the near future halfpenny certificates proving that the letters to which they referred had been posted, but the use of these certificates would be no substitute for registration. Another change to be shortly carried out affected the rates for foreign parcel post. This country exported more than £5,000,000 worth of goods in that way, and showed an increase of 60 per cent. in the last seven years. Many of the rates were higher than those charged by Germany. The English portion of the foreign parcel post rate was at present 5d. for parcels under 2 lb., 10d. for packets of less than 7 lb., and 1s. 3d. between that weight and 11 lb., and he proposed a reduction of about 50 per cent. in those charges. The loss to the revenue would be £19,000 a year, but that would, he was confident, be speedily recouped by growth of the business. On May Day he had the pleasure of sending and receiving from the Postmaster-General of Australia messages of congratulation on the coming into operation of the 1d. post from the Commonwealth to the United Kingdom, thus completing the system of Imperial penny postage with the exception of a few small islands in the Pacific.

Submarine Cable Communication.

The subject of ocean cable communication had been fully considered, and he had decided that the control of the rates should be secured by means of the licences granted for landing cables on our shores. As these licences came up for renewal they would set forth that if, in the opinion of the Government, cabling rates were excessive, formal objection would be taken to them, and if the owning company disagreed with this objection it would be referred to arbitration. He considered cable companies were entitled to much credit for their readiness to listen to representations made to them, particularly in one direction. They had all consented to a large reduction in the rates charged for plain language telegrams of a non-urgent character. He had been negotiating with all the leading companies with headquarters in England, and both the Atlantic and the Eastern group of companies had agreed to reduce their rates by 50 per cent. for telegrams in plain language. Arrangements were also being made for accelerating the telegraphic service between this country and the Continent by the adoption of new telegraphic appliances, and new cables would be laid where required.

Wireless Telegraphy.

The year had seen a rapid extension of the erection and use of wireless telegraphy. His predecessor (Mr. Sydney Buxton) purchased the coast stations belonging to the Marconi Co. and Lloyds, and these were now being operated by the Post Office. The purchase had proved wise and far-seeing. During the year the number of ships fitted with wireless apparatus had increased from 130 to 290. Marconigrams had increased 50 per cent. over the previous year. He now proposed to erect new stations at or near Newcastle-on-Tyne and on the island of Valentia. Wireless telegraphy, by a curious coincidence, had been brought prominently before the notice of the public by its use in the sensational murder case in which Dr. Crippen was concerned, and it would be remembered that the electric telegraph was originally regarded by the public as a toy, and it was not until a murderer, who had escaped from Slough, was apprehended as he was leaving the train at Paddington railway station, that the public took a real interest in the electric telegraph.

Digitized by Google

Telephone Transfer.

After Whitsuntide he hoped to be able to introduce the Telephone Transfer Bill. During the year there had been a satisfactory development of the Post Office telephone system, the increase representing 13 per cent., while the revenue from the trunk wires had increased by 15 per cent. Another interesting feature had been the laying of a submarine telephone cable of a new type between this country and France. This would afford improved hearing and would extend the length of telephonic communications with the Continent. He was waiting for the French Government to construct certain new land lines and to lay a new telephone cable, and when these additional facilities were available he hoped to be able to reduce by 50 per cent. the charges for telephonic communication between England and France. He was also endeavouring to develop in this country a system of rural telephones similar to that which existed in America, and the Post Office was offering the unlimited use of a telephone for £3 per annum to any farmer who was willing to join with his neighbours (there must be not less than five on a "party" line) in subscribing to the telephone system.

Conditions of Service of Employees.

After referring to the work of the Savings Bank Department, Mr. Samuel dealt with the question of the conditions of the services connected with the Post Office. In regard to the subject of remuneration, he said, impossible to go into isolated cases of the telegraphists in the largest towns, of the London sorters, or into matters connected with the other branches of the service; if any revision of the general position were to be made it must be a general revision affecting the whole staff, numbering now some 217,000 persons, who, when the National Telephone Co. was taken over, would be reinforced up to the number of 20,000. At the same time, however, he must agree that the recommendations of the Hobhouse Committee could not be allowed to stand for ever. The work of the telephone operator, it was agreed, put a great strain on the nervous system, and it was necessary to take steps to mitigate it as far as possible. He had consulted the medical officers and had arranged that certain improvements should be adopted. Some of the operators were employed for six hours one day and 10 hours another in order that the working of a particular exchange should be facilitated. This was too long, and would be abolished. Other improvements were in prospect, including an improved headgear. They were also experimenting with a special type of chair, so that operators and others need not be subjected to periods of continuous standing.

Finally, the right hon. gentleman dealt with the boy messengers and the future position of the lads who enter that service. The entire statement was received with much interest.

NEWCASTLE-ON-TYNE CORPORATION BILL.

The tramway clauses of this Bill were passed by a Select Committee of the House of Commons last week. On Friday it was explained to the Committee that the Corporation had come to terms with the Newcastle-upon-Tyne Electric Supply Co. and the whole of the questions between the Company and the Corporation had been settled. By the agreement the Corporation are to take all current required by the Corporation for any purposes outside the city boundaries, except for the existing tramway at Gosforth, at a price which would be found satisfactory to the Corporation.

COAL MINES BILL.

The Bill was further considered by Standing Committee B of the House of Commons on Tuesday.

Referring to clause 16, which provides for monthly inspection of mines by two workmen by two of their number or any two persons, not being mining engineers, who are practical working miners, Mr. MASTERMAN moved an amendment to provide that the practical working experience required must have had not less than five years' practical experience.

Mr. MASTERMAN proposed that workmen's inspectors should, in the case of an accident occurring in a mine, be allowed to go, "together with the representative of the workmen, or with a mining or electrical engineer appointed by the workmen," to the place where the accident occurred, and to make such inspection as might be necessary for ascertaining the cause of the accident. The men should have an opportunity of obtaining the best advice in case of accident. The men's inspectors, however, would not have any knowledge of scientific mining, or of the electrical working of a mine.

Mr. MASTERMAN accepted the amendment with the addition of the word "the" before "representative."

The clause, as amended, was added to the Bill, as were also clauses 17, 18, and 19.

Rural Telephones.—In the House of Commons on Wednesday the Postmaster-General (Mr. H. Samuel) stated, in reply to questions, that there would be no objection on the part of the Post Office to accept as subscribers to the proposed farmers' telephones other persons connected with the industries, who lived a considerable distance from a telephone exchange. In general, however, traders of various classes who lived in the vicinity of a telephone exchange would not find that it met the conditions of their business to share a line with a number of other subscribers, and the ordinary exchange lines were better suited for their requirements. If country doctors thought it convenient, and were able to meet the requirements as to these cheap telephones, he did not, as at present advised, see any objection to their inclusion in the scheme.

Greater London Railway Bill.—During the week a Select Committee of the House of Commons heard further evidence in favour of this Bill.

On Wednesday evidence was taken on behalf of the L. & N.W. Railway Co. in opposition to the scheme.

Mr. HERBERT WALKER, outdoor goods manager for the southern section of the L. & N.W. Co., challenged the financial figures of the promoters. To pay a dividend of 4 per cent. on the proposed ordinary capital of £4,000,000 the projected railway would have to earn a gross revenue of £533,333 per annum. That meant earning £177 per mile per week over the whole length of 57 miles, or £205 over the 50 miles which were given as a through run. This was considerably more than twice as much as the Great Eastern and 33 per cent. more than the Tilbury line earned. He did not think the railway would get one-fourth of the present dock traffic, but, even if it did, that would provide an annual revenue of something under £30,000.

Birmingham Extension Bill.—This Bill was finally passed by a House of Commons Committee on Friday and now awaits Royal Assent. The Bill extends the municipal boundary so as to include Handsworth, Aston, Erdington, Yardley and a portion of King's Norton and Northfield and the tramways and electricity undertakings in those districts will also be acquired by the Corporation.

LEGAL INTELLIGENCE.

British Westinghouse Electric & Mfg. Co., Ltd. v. Underground Electric Railways Co. of London (Ltd.)

This case came before a Divisional Court (Mr. Justice Pickford and Mr. Justice Lush) on Tuesday, on a motion by the British Westinghouse Co. to set aside an arbitration award in regard to an alleged breach of contract for the supply of turbo-generators to the Underground Co.

Sir A. Cripps, K.C., Mr. Disturnal and Mr. Tangye were for appellants, and Mr. J. Roskill, K.C., Mr. A. B. Shaw and Mr. L. Macassey for respondents.

Sir A. CRIPPS, K.C., said the question for the Court was of great importance, involving a complicated matter of law, and important also in relation to the amount of money involved, some £120,000. What he had to show in order to succeed was, first of all, that there was an error in law on the face of the award, and, secondly, that what had been done upon that matter of law on the face of the award was in itself bad. The main point which he raised on that, although very important, was a short one. Respondents (the Underground Electric Railways Co. of London) gave an order to the British Westinghouse Co. for the supply of certain turbines with motive machinery for the supply of electrical energy for their underground railway system. They supplied the turbines, but were told by the arbitrator that they were not in accordance with the terms of the contract. The breach had been admitted, and the question was as to how the damage in consequence of the breach should be settled. The question between the parties arose after the turbines were admitted to be bad so far as the contract was concerned. After they had been running for a time the Underground Co. substituted Parsons turbines, and appellants said that the measure of damages, under the circumstances, should be only the additional cost thrown upon them by running the Westinghouse turbines and substituting Parsons turbines. By the substitution they had mitigated the damage, a matter which ought to have been taken into account in the award. They were agreed that up to the point of the substitution of the Parsons turbines there had been damage; but appellants said that under the conditions disclosed in the substitution of the Parsons for the Westinghouse machine respondents not only mitigated the damage, but obtained a great benefit or profit for themselves which ought to have been considered in estimating the measure of damage. When they had got to that stage they asked the arbitrator (Mr. Lyttleton, K.C.) to state a case for the opinion of the Court. That case was stated and heard before the Divisional Court. For present purposes he would assume that the opinion of the Divisional Court was against him on the points submitted, but the question was how far benefit or profit was to be taken into consideration in estimating the true rate of damage. If their lordships thought that this Court would be bound by the opinion of the other Divisional Court to which the points were submitted by the arbitrator's case, then they would have to go to the Court of Appeal.

Mr. Justice PICKFORD said that the Court was of opinion that it ought to follow the decision of the other Divisional Court.

Sir A. CRIPPS said that the same points would arise as those which were discussed in the Divisional Court over which the Lord Chief Justice presided. If the arbitrator had followed the judgment he had not followed the advice given by the Lord Chief Justice.

Mr. Justice PICKFORD said that what the arbitrator would have to follow would be the answers to the questions which he had submitted for the opinion of the Court where they were answered by the judge specifically.

Sir A. CRIPPS said that the Lord Chief Justice had not answered the questions simply in the affirmative or the negative, because he did not think he would be doing justice to the case by so doing. The first point was whether, as a matter of law, they were entitled to bring to the mind of the arbitrator that the true cost was not what had to be paid, but whether they obtained beneficial results. In all cases of damage they came back to the simple test of cost in order to arrive at the true measure of damage. Respondents also contended that they were entitled to

Digitized by Google

recover the cost of the installation of the Parsons machinery. It was almost impossible to answer the questions submitted by the arbitrator with a simple "yes" or "no" apart from the context of the judgment. What appellants said was that they must ascertain the actual cost to which respondents had been put, bearing in mind that the Parsons machines had a larger scope than the old turbines, and could be worked much more economically. Owing to the march of invention, the Parsons machines were much better than the old ones, and could the arbitrator award as damages the whole cost of putting in a much better machine—machines which would work under conditions that would save respondents £20,000 a year?

Mr. Justice LUSH: You say that they are putting a heavy profit into their purse.

Sir A. CRIPPS said that it was not for the Court to say what the amount of the profit was, but the whole effect of the substitution must be taken into consideration. The arbitrator was entitled to take into consideration the effect of the Parsons machines, and he said that on that account mitigation of damages must be brought in. The arbitrator had stated a case on certain points of law, and judgment was given by the Divisional Court on those points, and that judgment formed part of the award. He could not imagine a more important point for discussion in a case of that kind than how to get at the true costs. To do that they must have the set-off of the benefit from profit.

Mr. Justice PICKFORD: You are really asking us to say whether the answers which appear on the record of the Divisional Court are right or wrong.

Sir A. CRIPPS said what he desired to argue was that, in face of the questions, it was impossible to answer them with a simple "yes" or "no." They were partly questions of fact and partly of law.

Mr. Justice LUSH said that the Court could only deal with the motion upon the assumption that there had been a mistake on the face of the award. If they could show that the arbitrator was not understood accurately by the Divisional Court then they could appeal; but that did not appear to be so in that case.

Mr. ROSKILL, K.C., for respondents, said that the Divisional Court, in giving their opinion, had answered certain questions, and from that decision he contended there was no appeal. He did not think it right that he should be kept out of the money because the other side wanted time. If it were decided to take the case to the House of Lords, there would be a delay of at least another year.

Mr. Justice PICKFORD: If you want security I have no doubt it can be given.

Mr. ROSKILL said that the costs were enormous, the out-of-pocket expenses alone amounting to some £13,000. The question of costs, apart from the question of security, was one which pressed rather hardly upon his clients.

Mr. Justice PICKFORD said that the reasonable thing would be for appellants to pay the costs under the usual undertaking.

The summons was then dismissed, with costs.

Telephone Agreements.

At Brighton County Court on Friday last Judge Scully delivered judgment in an action brought by the National Telephone Co. against a subscriber. The Company had removed their instruments from the premises of the subscriber (Mr. A. Romaine) who had given up his tenancy. The Company sought to make defendant liable for a year's subscriptions in advance.

His Honour held that the recovery of the instrument determined the contract, leaving defendant liable for any rent due up to that time, but not to any rent for a future period.

Anderson v, Cutts & Hoult,

In the Sheffield County Court last week Mr. T. Scott Anderson, consulting engineer and electro-metallurgist, claimed £100 damages from Messrs. Verdon O. Cutts and Ernest Hoult, engineers, of Sheffield, for the wrongful use and publication by them, to the prejudice of plaintiff, in a booklet entitled "The Electrical Manufacture of Steel in the Verdon Cutts and Hoult Electro-Bessemer Furnace," of information wrongfully collected by defendant Cutts whilst in plaintiff's service as clerk, from books, letters and other documents belonging to plaintiff. In the alternative, damages were claimed for infringement of plaintiff's copyright in books and documents from which material had been taken. An injunction was also asked for.

Mr. T. E. Ellison, for plaintiff, said that, after consultation, both sides were agreed that the publication of the pamphlet was one that could not be supported. Defendants had agreed to give an undertaking that no further publication of the pamphlet should be made, and that the copies which had not been circulated should be destroyed, and had consented to pay £10 damages and costs.

Mr. WADDY, for defendants, said both his clients were young men. Mr. Cutts when he left plaintiff started a business in competition with his old employer, as he was perfectly entitled to do. During the latter part of his employment with plaintiff a large amount of correspondence and technical work was entrusted to Mr. Cutts, and amongst other things he wrote for the purposes of a catalogue an article which afterwards found its way in a much altered form into the Verdon Cutts booklet. In those circumstances Mr. Cutts committed a mistake, and he accepted the position quite frankly. He took a wrong view of his legal position. Defendants willingly gave the undertaking mentioned by Mr. Ellison.

Judgment was entered accordingly.

Andrews v, Abertillery Urban District Council,

Last week the Court of Appeal allowed the appeal of plaintiff from an order of Mr. Justice Warrington dismissing plaintiff's action for a declaration that defendant Council were not entitled to place electric light standards on plaintiff's land at Llanhilleth. The facts of the case were reported in THE ELECTRICIAN for March 10 (p. 874), and the Court now granted a mandatory injunction to remove a standard erected on land not repurchasable by the public authority in front of plaintiff's house, and gave plaintiff costs of the appeal.

Johannesburg Municipal Council v. D. Stewart & Co. (1902) Ltd.)

In the Court of Session last week their Lordships of the First Division allowed an appeal of plaintiffs from an order of Lord Ormidale postponing the hearing of proof until October, defendants being liable for expense to which plaintiffs might be put.

The LORD PRESIDENT said their lordships were of opinion that the time allowed for the preparation of the case had been ample, and that it would really be a scandal to justice in that court if there was a further postponement.

London County Council.—On Tuesday the Highways Committee presented a report on workmen's cars, &c.

For the year ended March 31 last the receipts from workmen's electric car services amounted to £158,040, and the total expenses to £219,3[illegible] leaving a deficiency of £61,302. On the horse cars the receipts were £3,203, and the deficit £4,630. The report states that every mile run by a workmen's car is run at a loss, and they feel that if, apart from the normal increase in workmen's car-mileage, there is also an extension of the period within which workmen's fares are charged, the result from a financial standpoint is likely to be disastrous. Although there has been an increase recently in the car-mileage run on the Council's tramways, and an increase in the number of passengers carried, the result of concessions made from time to time to the travelling public has been to effect such a reduction in the net revenue per £100 of capital expended, that a point has been reached when further concessions would be very unwise, at any rate for the present, if the tramways are to be maintained on a self-supporting basis.

The estimates of the tramways undertaking for the next financial year were also submitted by the Highways Committee, who had put the total capital expenditure to the end of March at £11,600,000, and it is estimated that a further sum of £2,400,000 will be required to complete the work of electrification and the construction of authorised tramways. As a result of the working of the electric lines during the coming year, the estimated surplus is £915,690, and an estimated deficiency of £14,805 on the horse lines, making a net surplus on working of £900,885, to which has to be added £11,500 representing interest on bank balances and sundry receipts. The expenses and capital charges are estimated at £724,541, leaving a net surplus of £187,844, of which it is proposed to apply £138,270 to renewals fund and £49,574 to general reserve.

Practically the whole of the new tramways for which Parliamentary authority has been obtained had been constructed, but it was not possible in regard to many of the routes to carry passengers right through to their destination. This difficulty would be met as regards many of the routes if the present termini could be linked up with one another, or the lines extended to some well recognised traffic point, and that was a question to which the Committee were giving careful consideration. The Committee made a considerable point of omnibus competition, and also as to the advantages enjoyed by such competitors in having to pay nothing for the use of the roads and also to the fact that they choose only the routes, whereas many of the tramway routes were in localities where the traffic was only good at certain hours of the day.

The Finance Committee, in their report on the estimates, say that the estimated surplus balance for 1911-12 is less than the revised estimate of the surplus for 1910-11, notwithstanding further large expenditure on capital account during the year, and also that the surplus originally estimated for 1910-11 will not be realised. The falling off of passenger receipts, which was responsible for the reduction of the surplus, was largely to the wet and cold summer and autumn months. It appears to be desirable that the Council should bear in mind the possibilities of other forms of traffic adversely affecting the passenger receipts of the Council's tramways. Although the receipts had not been maintained at the original estimate of 1s. a car-mile, it had until recently been anticipated that by economies in working a surplus of 5d. a car-mile might still be looked for. From the figures in the 1911-12 estimates it appeared that a lower figure would have to be substituted, and the estimates provide for a figure of 4½d.

A lengthy discussion took place on the report, and several amendments were moved to the effect that the electrification of the remaining portions of the system should be proceeded with without delay, but these were rejected and the report adopted.

Light Railways.—The Merthyr Electric Traction and Lighting Co. are applying for an order amending their 1899 order by substituting 35 for 25 years as the period during which the order will be in force, and authorising an agreement with Vaynor and Penderyn Urban District Council.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Amalgamated Association of Tramway and Vehicle Workers.—The 21st annual conference of this Association was held at Newcastle-on-Tyne last week.

Mr. SPEAKMAN, in the course of his presidential address, said the increase in membership was a record. The improvements in the conditions of the labour of a large percentage of the members was satisfactory. The process of speeding-up, of putting cars upon the road of an ever-increasing carrying capacity, of inter-running with other tramway undertakings, of increasing the number of tickets and other increases, called for serious consideration and action in the direction of obtaining more time for leisure and recreation. Members should also work to reduce the length of time between the minimum and maximum rates of pay. The concessions obtained by Northampton and Salford, and the aims and objects of the Manchester branches, to reduce hours of labour, appealed to him as most consistent. There was undoubtedly a growing desire on the part of tramway authorities not to be content unless huge profits could be made and handed over to relief of rates. That lent itself to the perpetration of many evils, and it was becoming increasingly difficult for tramway employés to obtain even slight improvements by which they might be able to do their work with more ease and comfort. Facts went to prove that there was a greater need for continuous activity in developing their organisation.

Birmingham.—At the last meeting of the Council the salaries of Mr. J. McDonell, traffic superintendent, and Mr. S. B. N. Marsh, assistant of the tramways department, were increased from £250 to £300 per annum.

Cathedral Lighting.—The cathedral church of St. Giles, Edinburgh, has recently been provided with an electric lighting installation, under the direction of Mr. R. S. Lorimer, A.R.S.A.

Derby.—An unopposed inquiry was held last week into the Council's application for sanction to borrow £8,500 for extensions of the electricity undertaking.

The Town Clerk (Mr. G. T. LEE) said that the application was made in connection with the estimated capital expenditure for the year, and it was necessitated by the continued growth of the business. The total output was now 5,573,706 units per annum, an increase in 12 months of 630,000 units. That was the largest increase since the works were started. Last year there was a slight loss of £78. 18s. 4d., due to the fact that there was no particular output from the new power station. Although the year's accounts had not been completed, it was certain that there would be a large net profit. The outstanding debt was £217,915, which was a reduction of £93,624 having been paid on repayment of capital.

Eston.—The Council have appointed a sub-committee to report upon a communication from the Cleveland & Durham County Electric Power Co. as to the supply of electricity in the district.

Inquest.—An adjourned inquest was held last week on two platelayers named Christy and Young, who were killed in the Duffryn Woods, Aberewmboi, on the 9th inst. Mr. W. N. Atkinson, chief inspector of mines, represented the Home Office, and Mr. R. Nelson, H.M. electrical inspector of mines, was also present.

W. CATHWAY, foreman platelayer of the Powell-Duffryn Co., said the deceased men worked in his gang, and on the 9th inst. they proceeded to the Duffryn Woods to prepare some holes for electric standards. Witness noticed a lot of smoke rising higher up in the wood, and he sent Young to enquire into the cause of it. Later he sent Christy to a neighbouring farm to fetch some tools. He had to walk in the same direction as the men had gone. Subsequently the two men were found lying dead in a line to the electric pole, which had caught fire.

FRANK GARDNER, another platelayer, found the two men dead. Christy was sitting at one of the electric stays.

Mr. GEORGE HANN, deputy general manager of the Powell-Duffryn Co., said one of the insulators on the pole, near where the men were found, was somewhat loose, with the result that the current leaked to the stay and ignited the pole. That had caused the fire. He was of opinion that the insulator had come loose on account of the pulling of the wire.

W. COOPER, foreman at Powell-Duffryn power station, said the voltage on the line was 3,000.

Mr. NELSON: The leakage was not sufficient to cause the relays to act.

ARTHUR FLANDERS, electrical engineer, stated that the voltage of the line at the time of the accident was 1,850.

ROBERT THOMAS said the line was in perfect order after the erection of the new pole on the night preceding the accident. The new pole was about 3 yards higher than the pole next to it.

A verdict of death by misadventure was ultimately returned.

Loughborough.—An unopposed inquiry was held on Friday into the application of the Council for sanction to borrow £2,310 for extensions of the electricity undertaking.

Mine Rescue Work.—The Home Office has issued a draft order under the Mines Accidents (Rescue and Aid) Act, 1910, as to the formation of rescue brigades in mines.

The order states that rescue brigades consisting of not less than five persons employed at the mine, selected on account of their knowledge of underground work, coolness and powers of endurance, and certified to be medically fit (a majority of whom shall be trained in first aid and shall hold a certificate of the St. John's Ambulance Association or of the St. Andrew's Association) shall be organised and maintained at every mine as soon as is reasonably practicable. These rescue brigades are to be on the scale set out in the order, which further directs that sets of portable breathing apparatus in the proportion of two sets to each rescue brigade shall be maintained at every mine. At every mine which maintains a rescue brigade there must be provided two or more small birds or mice for testing for carbon monoxide; two electric hand-lamps for each brigade; one oxygen reviving apparatus; a safety lamp for each member of the rescue brigade for testing for firedamp; and an ambulance box. It is also required that at each central rescue station not less than 15 complete sets of breathing apparatus shall be maintained, together with 20 electric hand-lamps and four oxygen reviving apparatus. A motor car is also to be kept in constant readiness.

National Association of Colliery Managers.—The British Westinghouse Electric & Mfg. Co. took advantage of the annual meeting of this Association at Manchester on May 18, 19 and 20 to invite the members to pay a visit to their works and inspect some of their apparatus particularly suitable for mines.

A good number of members availed themselves of the offer, and made a tour of the shops under the guidance of several Westinghouse engineers. A special exhibition of mining switchgear had been arranged, including a complete line of 750, 3,300 and 6,600 volt mining switch pillars, also examples of type "S" gate end switch boxes, specially designed for use in shallow headings; oil switches, circuit-breakers, auto-starters, liquid starters, controllers, rheostats, &c. A variety of switchboards of all types was seen going through the shops, and full access to details of manufacture was freely given. There were also on view steam turbines, condensers with Leblanc air pumps, turbo-blowers, r.t. Moore turbine-driven high lift pump for 400 g.p.m. against 827 ft. running at 3,000 r.p.m., large and small gas engines, motors, generators and other apparatus, including two-speed motors, 180 H.P., 400-volt d.c. driving Worthington hydraulic pump 250 g.p.m., 800 lb. per sq. in. for L. & N.W. Railway's London-road station.

National Electrical Manufacturers' Association.—Next meeting of Council will be held at Balfour House, Finsbury-pavement, E.C., June 1, at 2:30 p.m.

Osram Lamps in the French Navy.—The French ironclad "Vérité," upon which the President of the French Republic shortly starts upon his voyage, is illuminated throughout by Osram lamps.

Poplar (London).—Application is to be made to London County Council for a loan of £42,455 for the electricity undertaking.

A new agreement is to be entered into with the Port of London Authority for supply of electricity to the docks for nine years. The Port Authority will take 750,000 units per annum for general use with a maximum demand of 150 kw. on the Council's peak, and about a further 100,000 units per annum for Millwall dry dock pumps, with a maximum demand of 350 kw., but the dry dock main pumps shall not be worked upon the Council's peaks, the peaks to be considered as being between 4 p.m. and 6 p.m. on week days in November, December, January and February. The price to be 0·60d. per unit for direct current at 230 and 460 volts.

Presentation.—Harrogate electricity staff have presented Mr. W. Firth, jointer, with a gold watch on his departure for Australia.

Provisional Order Revocation.—The Board of Trade have revoked the Clitheroe Electric Lighting Order, 1904, as from May 13.

St. Helens.—An inquiry was held on Tuesday into the application of the Council for sanction to borrow £10,800 for extensions of the electricity undertaking.

The borough electrical engineer (Mr. E. M. HOLLINGSWORTH) stated that the loans sanctioned to date amounted to £175,157. On Sept. 2 last sanctions were obtained for £10,206, but only £6,000 of that had been borrowed. Most of the work then sanctioned had been completed and they were overspent by nearly £1,600, for which they would have to apply for leave to borrow.

The inspector (Major STEWART) asked what had caused the tremendous jump this year in the demand for electric current.

Mr. HOLLINGSWORTH said that they supplied many of the small works of the town, and several of the large manufacturers had come on during

Digitized by Google

the last 12 months. It was due to the general application of power. People were finding out the great advantages of electric driving.

After going through the figures, the INSPECTOR remarked that it was evident that there was a need for more plant at the works to meet all the demands. He commented on the low cost of production at the works. When they first started the cost was 6·33d. per unit, but it had now gone down to 0·65d. per unit.

Stockton-on-Tees.—The Council have decided to carry out extensions of the electricity works at an estimated cost of £6,000 and £7,000. The scheme has been prepared by the borough electrical engineer, Mr. J. J. Smith.

Trowbridge.—The Council have referred to the Electricity Committee an application by the local electric supply company for sanction to use overhead Dires for the uspply of electricity to private consumers.

Walthamstow.—The price of current to lighting consumers is to be reduced by ¼d. per unit, and an equivalent reduction is to be made for current supplied under the Osram lamp maintenance scheme.

The inclusive arc lighting rate is to be reduced from £4 to £3. 15s. per flame lamp of 500 hours burning, and £3. 10s. for enclosed type lamps.

Application is to be made to the L.G. Board for sanction to borrow £5,149 for laying a feeder cable.

Permission has been given to the Premier Advertising Co. to erect cabinets in various parts of the district, and these cabinets are to be supplied with current at 2d. per unit.

Wigan.—On the 16th inst. two electrically-driven centrifugal pumps at the pumping station were started by the chairman of the Water Committee (Ald. Richards). The pumps were supplied by Rees Roturbo Mfg. Co.

Wood Green.—The Council are taking a plebiscite of the ratepayers on the question of entering into an agreement with the North Metropolitan Electric Power Supply Co., for a supply of electricity in bulk.

COLONIAL AND FOREIGN NOTES.

Argentina.—The "Review of the River Plate" says "a concession has been granted to the Empresa Telefónica del Chubut, Richelet y Ca., for 30 years for the provision of telephone lines in Comodoro Rivadavia. The National Government may expropriate at any time by payment of capital cost, plus 15 per cent.

Electricity supply works and electric tramways are to be established at Necochea.

Gandulfo & Co. have asked the Provincial Government to rescind the decree which declared lapsed their concession for the construction of an electric tramway between Evellaneda and La Plata.

It is stated that the syndicate represented by Mr. Herlitzka, and in which the French Bank of the River Plate is interested, has obtained a controlling interest in the Anglo-Argentine Electricity Co.

Australasia.—H.M. Trade Commissioner, Equitable Building, Melbourne, has applications from Australian firms desiring to represent British manufacturers of machinery, engine packing, electric light fittings, &c.

Adelaide Council propose giving notice of intention to purchase the undertaking of the Adelaide Electric Supply Co. prior to the date authorised by the Act under which the company are working (Dec. 11, 1911). The company decline to accept the notice prior to that date, and the Council may promote a special bill to give more liberal terms.

Mr. E. H. McKinney, formerly hydraulic engineer to the Government, has suggested that an electric power scheme should be combined with the extensive irrigation scheme which is being carried out at Burrinjuck (N.S.W.). Mr. McKinney estimates that £10,000 would cover the cost of the power stations and plant, and that the whole of this capital could be redeemed in one year by the receipts from sale of energy. He estimates that 10,000 H.P. can be obtained from a dam now under construction on the Murrumbidgee river.

The Mount Lyell Mining Co. (Tasmania) propose to generate electrical energy by water power obtained from Lake Margaret.

Perth (W. Australia) City Council have complained that the Perth Electric Tramways (Ltd.) give an insufficient service. The company state that this is due to the practical prohibition of overtime by the award of the Arbitration Court in the dispute between the company and its employés.

The Royal Commission on (Melbourne) Suburban Traffic recently took the evidence of Mr. A. F. Showers (Mayor of Essendon), who said he was of opinion that any profits from the tramways should be devoted to extensions and the profits should be apportioned according to the municipal valuation and not on a car-mile basis. His Council had endeavoured to secure a conference for the appointment of a Metropolitan Council to control all matters common to the metropolis, such as tramways, electricity supply, &c. Railway electrification would take people away from the congested areas and would be an effective way of meeting tramway competition. The reason the Essendon tramways were not paying more than working expenses and depreciation was that they were not linked on to the Melbourne lines. The Mayor of Brighton (Mr. Edmonson) and Mr. F. Ferdinando (Moorabbin Shire Council), who also gave evidence, were in favour of municipal control of tramways, and opposed the conference scheme of representation and distribution of profits.

Mr. A. BATSON (town clerk), of Fitzroy, said his Council was in favour of municipal ownership of tramways. The Councils required the revenue from tramways for relief from taxation. He did not think it desirable to take over the present tramways before the expiration of the lease. The Mayor of Richmond (Mr. D. L. Davies) gave similar evidence.

Mr. R. P. WILSON was re-called, and dealt with the proposed re-grading and duplication of the Caulfield and Camberwell lines. He said these alterations were necessary under the present steam system, but could be avoided by adopting electric traction. He proposed the d.c. system at 800 volts. If the electrification scheme had been in force the department would have increased its profits by £60,000 during the present year, and next year the increase would have been £80,000. Mr. Wilson subsequently repeated this evidence before the Railways Standing Committee.

Mr. Fredk. Black, electrical engineer, of Wellington, N.Z., has been engaged to report on the electrical plant and power required at the Ross Goldfields (Reconstructed), Ltd.

Mr. P. J. Pringle, general manager of the Electric Supply Co. of Victoria, has informed the motormen and conductors on the company's Ballarat tramways that he cannot concede their demand for wages of 8s. per day. A wages board will shortly deal with the question.

Eaglehawk (Victoria) Council have accepted tenders at par for the loan of £6,000 for the equipment of electricity works.

A deputation of the Kadina and Wallaroo (S. Australia) Councils recently waited upon the Premier of South Australia and advocated the erection by the Government of an electric power station at Wallaroo. It was stated that Kadina Council had erected a station but could not cope with the demand for energy. Wallaroo Council at present purchase electricity from Wallaroo & Montana Smelting Co. at 5d. and 4½d. per unit, on a sliding scale, and retail it at 6d. The Premier said the proposal would form part of a scheme for supplying power and light at Wallaroo railway yard and jetty and other places, and he hoped to introduce a Bill next session.

Electric coal cutters have been tried in the Cullen Bullen (N.S.W.) Invincible Colliery, have been found satisfactory, and are to be permanently adopted.

The Mayor of Auckland (N.Z.) recently performed the ceremony of driving the corner pile of the Corporation's new electric power station. The Council have raised a loan of £225,000 for extension of their electricity undertaking.

Queensland Electrical Energy Supply Co. propose to supply current to Cairns, Bundaberg, Mackay and Warwick. Bundaberg and Warwick Councils have given their assent conditionally. Cairns Council recently refused assent to a similar proposal by a company.

Mansfield (Victoria) ratepayers have asked the Shire Council to secure a supply of electricity in the town.

Melbourne Electric Supply Co. have commenced the laying of mains for the electric lighting of Camberwell.

An agreement has been signed for the supply of electricity by the Melbourne Electric Supply Co. to Hawthorn (Victoria) Council for 14 years, after which date the works can be acquired by the Council.

Ararat (Victoria) Council have been informed that a supply of current for lighting the local asylum would be taken from the proposed municipal electricity works, and the Council will probably proceed with the scheme.

Manly (N.S.W.) Council, who own electricity works, have given a guarantee to a new company formed to extend the system to additional streets, beaches, &c.

Goulburn (N.S.W.) Council are seeking authority to establish electricity works, and Mr. J. E. Donohoe, of Balmain Electric Lighting Corpn. is preparing a report on the matter.

A committee of Tenterfield (N.S.W.) Council was recently appointed to consider the question of public lighting by electricity or gas.

Austria-Hungary.—Ganz & Co. are about to extend their works at Budapest at a cost of about £104,000.

Miskolez municipal authorities have decided to establish electricity works at a cost of £25,000.

Brazil.—A Consular report states that imports at Bahia during 1909 included machinery to the value of £134,388 (compared with £125,315 in 1908), rails and accessories £42,694 (£45,890), electric cables £11,658 (£2,149), wire £23,496 (£19,156) and electrical appliances £35,697 (£52,500).

Franco-Spanish Electric Railway.—The completed portion of the electric railway from Villefranche and Vernet-les-Bains to the Spanish frontier, upon which £1,280,000 has been expended, is to be opened about mid-June for public service. The line is the property of the French Midi Co.

Hospital Lighting, &c.—The new General Hospital, Rangoon (India), which, with the nurses' home, &c., covers 23½ acres, and cost about £272,000 to build, is lighted electrically throughout by an independent steam-driven plant, which also supplies power to 270 punkahs, numerous small fans, large ventilating fans in the main building, paying patients' blocks and special nursing wards; also for working five lifts, two sets of refrigerating plant and the electric sterilisers and heaters and the X-ray and electro-therapeutic installation.

Italy.—The Soc. Anon. des Tramways de Bologne has recently obtained authority to extend their Bologna electric tramways.

Digitized by Google

Montenegro.—It is stated that the Government have recently granted concessions for the electrification of the Antivari-Virpazar railway, the construction of certain electric railways, and the erection and equipment of hydro-electric works.

Roumania.—The communal authorities of Slatina have obtained permission to borrow £32,000 for electric lighting, water supply, &c., and for purchase of tramway material.

Russia.—The British Consul at Batoum states that a British electrical engineer has applied for permission to promote a scheme for utilising river and lake waters in the highland districts of the Caucasus for the generation of electrical energy. The proposals include hydro-electric stations at Lars on the road beyond Vladikavkaz and on Lake Gotchkha for the Northern Caucasus and the trans-Caucasus respectively. A technical commission appointed by the Government has approved the principle and has drawn up conditions.

Spain.—La Electricidad has been formed, with a capital of £37,000, to take over and enlarge Messrs. Frêne, Agazzi & Co.'s electricity works at Sabadell.

La Electra Valenciana has been formed at Valencia, with £83,000 capital, to distribute electrical energy generated by the Hidro Electro-Española.

Turin International Exhibition.—The British section of this Exhibition was informally opened to the public on 19th inst. The official inauguration of the section will take place later.

Uruguay.—The bill providing for harbour improvements at Montevideo has been redrafted. An electric power installation, to cost about £24,450, is included, but this portion of the works will not be put up to public tender.

The Finance Minister of Uruguay recently requested the director of the Government electric light station at Montevideo to make a report on all existing electric light stations throughout the country, with a view to their nationalisation, and to formulate a project for establishing other stations.

Wireless Telegraph Notes.—We referred last week to the excellent service rendered by the wireless telegraph service on board the *Yarrowdale*, which was sunk as the result of a collision off Cape Henry, Virginia. We now learn that the equipment which performed this good service was supplied by the United Wireless Telegraph Co. of New York.

According to the "Pall Mall Gazette," the naval airship which was launched at Barrow on Monday is to be provided with a wireless installation. The report states that a special set of instruments has been designed and will be experimented with in due course.

The Australian Commonwealth Meteorological Department appears to have had a shock. Arrangements had been made for the exchange of wireless messages between the services and mercantile vessels to enable reports to be made of weather developments, but, although there being no land stations, only one message had been received at the time the report we are commenting upon had come to hand. This report was followed by an account for 50s., but the cost of this rather expensive start—in fact, unless the shipowners are prepared to assist the Meteorological Department in a spirit of liberality and philanthropy there is some likelihood that the collection of these messages will be delayed for a time. Under the arrangements made by the Australian shipping companies with the installations on their boats a royalty has to be paid to the Government on every message sent, and it is argued that should the proposal to utilise the existing ships for reporting meteorological conditions be carried out the Government must be prepared to bear a large share of the cost. A large number of the vessels on the coastal trade between Melbourne, Sydney and other Commonwealth ports are already equipped with wireless apparatus.

Two wireless telegraph installations have been erected in German East Africa, one on the shores of Lake Nyanza, one at Bukoba and the other at Mueaze.

A statement having been circulated that there would be communication between the Eiffel Tower Paris, and Canada during the Coronation proceedings in England, when, it was stated, M. Fallieres would exchange messages with Sir Wilfrid Laurier, the Canadian Premier, the Marconi Co. write to say that it is not possible to send messages to Canada from the Eiffel Tower, nor have any messages been transmitted, the only station capable of carrying out the operation being the Marconi trans-Atlantic station at Glace Bay, Canada.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Birmingham.—The annual reports and accounts of the electric supply and tramways departments were approved by the Council on Tuesday.

In presenting the accounts of the Electric Supply Committee, Mr. Cox said that the progress of the department during the past year had been considerable. There had been an increase of 30 per cent. in the units sold for private supply, and considering they had now reached very large figures in respect of output, a percentage like that was very satisfactory. It was principally for power supply, and the demand seemed to be as brisk as ever. The tramway supply had fallen by 9 per cent., due to the more economical use of current by the motormen since meters had been placed on the cars. The Tramway Committee would have two more routes open later in the year, and they were hoping to show an increase again in 1912. They had generated 4,000,000 units of current more at a cost of only £700 more than last year. That showed the value of a large load factor. He thought they had pretty nearly reached the limit of economy in generating cost. There were only four towns in the country to beat them—Bradford, Sheffield, Leeds and Stalybridge. Liverpool, Manchester and Glasgow were behind them in that respect. Rates and taxes had increased from £5,746 to £14,822, due to reassessment. At present they were the highest rated supply department in the country according to their size. The gross profit (£115,375) might strike them as large on a turnover of just over £200,000. It showed, however, they were not selling current under cost, and he did not think it was excessive considering they had such heavy capital charges to meet. Next year he thought they would have no further outlay in regard to reconstruction, and they would perhaps have recovered to some extent from their reassessment. After providing for interest and sinking fund, the net balance was £35,449. 4s. 9d., and of this sum the committee had carried £20,000 to renewals fund, leaving a surplus of £15,449. 4s. 9d., which it was proposed to pay to the credit of the Improvement rate, an increase of £5,193. 14s. 9d. The net increase in lamp connections (lighting only) amounted to an equivalent of 10,331 16 c.p. lamps, against 13,378. The net increase in motors connected was 5,344 H.P. (3,987 kw.), against 5,720 H.P. (4,267 kw.). The total length of new mains laid during the year as 14,063 yds., against 20,680 yds. The committee recommended that the following alterations in the charges for high-tension current be made, to take effect from the next quarterly meter readings: (1) That consumptions be calculated on a quarterly basis instead of an annual one, (2) that a reduction from 1d. to 0·95d. per unit be made to consumers using between 62,500 and 125,000 units per quarter, and from 0·9d. to 0·85d. per unit to consumers using between 187,500 and 250,000 units per quarter; (3) that the existing rates be extended so as to provide for a charge of 0·65d. per unit to consumers using between 750,000 and 1,000,000 units per quarter, and of 0·625d. per unit to consumers taking 1,000,000 units and upwards per quarter. In March, 1909, the committee pointed out, that special rates were being quoted with the consent of the Council in respect of exceptionally high load factors. At that time it was not possible to arrange a schedule of rates, as each case had to be dealt with according to the particular circumstances. The committee have now had sufficient experience to enable them to prepare such a schedule for consumers with load factors of 40 and 60 per cent.

The Tramways Committee reported that the capital for the year ended March 31 was £13,163 for reconstruction of Bristol-road route, &c.

Gross profit was £122,503, compared with £111,990 in 1909–10, increase £10,513. The committee decided to allocate £41,000 to relief of rates and place £24,000 to reserve, the balance being required for payment of interest and sinking fund. The use of meters on the cars resulted in a saving of about £5,000 for the nine months during which they had been in use. The number of passengers carried on the city lines was 84,727,449, against 81,310,868. There are 56 miles 67 chains of single tram track belonging to the department, and the average traffic revenue per car-mile was 11·58d., against 11·63d. last year, the total revenue being £318,882, against £308,283. Working expenses were £196,379, against £196,293, and the average expense per car-mile was 7·300d., against 7·569d. The average fare paid per passenger was 0·9d., and the average cost per passenger 0·8d., same as in the preceding year. The number of car-miles run on the city lines was 6,536,471, compared with 6,292,009; and the number of car-miles run inside and outside the city was 7,575,662, against 7,339,693. The percentage of working expenses to receipts was 61, against 64 per cent. The whole of the cars are to be provided with top covers before the commencement of next winter. The leases of the Bristol-road and Hockley lines to the City of Birmingham Tramways Co. will expire on June 30 next, and from that date the lines will be worked by the Corporation, who have to purchase the rolling stock, feeders and overhead equipment. It is intended to convert the cable tramways from Colmore-row to Hockley Brook to the overhead system. The standards and overhead wires are being erected, so that the new system may come into operation on July 1, though the reconstruction of the permanent way will have to be carried out subsequently. In connection with these two routes and the doubling of Garrison-lane route, the following additional capital will be required: Rolling stock (including 60 new cars and 130 top covers), £61,379; reconstruction of track (Colmore-row to Hockley Brook) and doubling of portion of Garrison-lane tramway), £31,928; overhead equipment, £2,714; feeder cables and switch pillars for Hockley route, £2,585; additional machinery and plant, £1,200—total, £99,805. In addition a further sum will have to be borrowed when the amount payable to the Company has been ascertained. The committee have arranged with Handsworth Council (which from Nov. 9 next becomes part of the city) for the working of the tramways in Handsworth as between July 1 next and Nov. 9.

Exeter.—For the year ended March 31 the receipts of the electricity undertaking were £18,286, working expenses £8,895.

Gross profit was £9,391, and after payment of interest and sinking fund, &c., the surplus was £2,333. The reserve and renewals fund amounts to £9,204. 6s. 9d. The number of consumers increased by 121 in the past year. It is recommended that the charge for current for private lighting be reduced from 4½d. to 4d. per unit.

Digitized by Google

The total tramway receipts were £16,165. 17s. 8d., a decrease of £763. 4s. 7d. compared with 1909-10. Current consumption has been greatly reduced by the use of meters, 62,554 units less than last year having been used, although 2,120 more car-miles were run. The charge for current has been reduced by ¼d. per unit, a saving of £203.

The accounts were approved by the Council on Wednesday.

George Town (Penang.—The report of the municipal electricity department for 1910 states that a new 300 kw. British Westinghouse steam dynamo and a Babcock boiler were put in service and the erection of the new condensing plant, including Korting motor-driven pump and Rees Roturbo equipment, was nearly completed.

There are 603 private consumers (increase 180), the equivalent 30-watt lamps connected being 7,755. The metal filament lamp has had an entirely beneficial effect on the undertaking, as the greater efficiency of the new lamps has led to a rapid increase of small consumers. Supply was given for a 7-ton crane used in building the Swettenham pier extension, and the resident engineer for that work reported that the working costs of the crane were 26·37 per cent. less than those of a steam crane of the same capacity. There were 842 fans connected. Revenue was $134,863·52, after deducting rebates, &c. (increase $21,633·73). Works costs were $64,548·11 and total costs $78,680·64, a decrease of 0·09 cents. per unit sold. Net profit was $9,697·64 (against $1,961, in previous year).

The receipts on the tramways were $81,1319·76 (against $65,381·75), operating costs were $61,324·91 (increase $1,060·07), and the gross profit was $19,994·85 (against $5,116·91), or about 4·2 per cent. on the capital expended. 2,638,517 (2,040,047) passengers were carried and 335,213 (281,412) car-miles run. Traffic revenue per car-mile was 24·22 cents (23·23 cents) and operating costs were 18·29 cents (21·42 cents).

Grimsby.—The accounts of the electricity department for the year ended March 31 show capital expenditure £106,817 (increase £4,499), of which £82,282 is outstanding.

Year's revenue was £21,421 (compared with £19,486 in 1909-10), gross profit was £10,848 (£10,043), capital charges were £6,262 (£6,176), and net profit was £4,586 (£3,867). Coal cost 0·244d. (0·270d.) per unit sold, generation costs were 0·511d. (0·607d.), distribution 0·055d. (0·046d.), and management, &c. 0·325d. (0·268d.). The total cost, 0·871d. (0·921d.), is the lowest on record, although rates and taxes increased £580. There are 1,006 (803) consumers, and units sold were 2,750,847 (2,350,869). After meeting out of the net profit the cost of alterations in street lamps (£9.05) and cost of new meters (£502), it is proposed to contribute £509 to rates in each of the two next half-years, and to transfer £1,890 to reserve. Sales of current for power purposes increased by over 30 per cent. The coal used was 7·31 lb. (8·36 lb.) per unit sold, a saving of 12 per cent., of which 10 per cent. (five-sixths of the saving) is attributed to the superheaters.

Heston and Isleworth (Middlesex).—The accounts of the District Council's electricity undertaking for the 15 months ended March 31 show capital expenditure £61,327 (increase £4,398), of which £8,911 has been repaid.

Revenue was £10,387 (compared with £7,861 for 12 months to Dec. 31, 1909), working expenses £4,784 (£3,733), gross profit £5,603 (£4,128), capital charges £4,791 (£3,687) and net profit £812 (£441). Units sold were 854,754 (against 605,616), of which 329,059 (228,271) were for power, 257,611 (172,398) for public lighting and 267,904 (204,947) for private lighting. There are 781 (646) consumers, and the equivalent 32 watt lamps connected for private lighting are 27,274 (24,715) and for public lighting 2,031 (1,879). The motors connected aggregate 408 H.P. (337 H.P.). The maximum load was 432 kw. (405 kw.), and the combined load factor 18 per cent. (17 per cent.). Fuel cost 0·37d. (0·44d.) per unit sold. Generation costs were 0·73d. (0·84d.), and total costs were 1·11d. (1·21d.).

Loughborough.—The accounts of the electricity department for the year to March 31 show capital expenditure £32,685 (increase £549).

The year's revenue was £4,213 (compared with £3,301), working and general expenses were £2,339 (against £2,447), and gross profit was £1,874 (£854). Capital charges were £2,335 (£2,401), and there is now a balance at debit of net revenue account of £1,074 (£2,215). There are 401 (336) consumers, and the total connections are equal to 29,764 (26,653) 8 c.p. lamps; units sold were 531,886 (357,129). There are 99 (90) motors of 517 H.P. (480 H.P.) connected. Works costs were 0·419d. (0·563d.) and total costs 0·569d. (0·909d.).

Sutton Coldfield.—The accounts of the electricity department for the year ended March 25 show capital expenditure £46,459 (increase £3,863), of which £11,268 has been repaid.

Revenue was £5,917, working and general expenses were £2,651, gross profit was £3,191, and net profit £173, and this, with a balance of £292 brought forward from previous year, is carried forward. Units generated were 470,810, of which 90,100 were supplied to public lamps, and 300,706 to private consumers by meter. The total maximum supply was 256 kw.

Sydney (N.S.W.)—The income of the electricity department for 1910 was £166,046, and the balance, after meeting working costs, interest and sinking fund, depreciation (£17,774) and preliminary expenses (£301) was £24,712.

The City Electrical Engineer and City Treasurer recommend that 50 per cent. of this surplus be written off goodwill of purchased companies, 45 per cent. be placed to renewals and replacement account, and 5 per cent. carried forward. The debenture account was increased by £190,000, making a total of £750,000, the other liabilities including purchased companies (£56,956), bringing the total liabilities to £958,367. The assets include plant £708,888.

Warrington.—The accounts of the tramways department for the year to March 31 show capital expenditure £102,128 (no increase). £22,573 has been repaid and £9,064 placed to reserve.

The year's revenue was £20,775 (£20,169), working expenses were £12,528 (£11,406), and net profit (after providing for capital charges) was £2,344 (£2,750). 5,375,572 (5,206,980) passengers were carried, 438,884 (435,774) car-miles run and 528,220 (528,139) units used. Average total revenue per car-mile was 11·360d. (11·108d.), and working expenses were 6·850d. (6·281d.), including power.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1911 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 24th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1911 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

The Council of the Metropolitan Borough of POPLAR invite tende for supply, delivery and erection of one 3,000 kw. turbine alternato complete with surface condensing plant; two water-tube boile with superheaters, air heaters, fans and chimneys; one 30-ton ele tric overhead travelling crane and water softening plant. Specific tion and form of tender from the borough electrical engineer a manager (Mr. J. Horace Bowden), Glaucus-street, Bromley-by-Bo E. Tenders to the town clerk (Mr. L. Potts), Council Offices, Hig street, Poplar, London, E., by 10 a.m. Monday, June 19. See also advertisement.

OLDHAM Corporation Electricity Committee invite tenders for t supply, erection and delivery of one 1,200 kw. mixed-pressure ste turbine, coupled direct to two d.c. generators in tandem, togeth with barometric condenser, pumps, &c. Copies of specificatio general conditions, &c., from the borough electrical engineer, Mr. Wilmott Newington, Greenhill, Oldham. See advertisement.

Tenders are invited (up to June 27) for supply of 1,400 protecto for use on main distributing frame at magneto exchanges to t Postmaster-General's Department, VICTORIA. Tender forms a specifications at the Commonwealth Office, 72, Victoria-stree London, S.W. See also an advertisement.

HAMMERSMITH (London) Borough Council invite tenders supply and erection of high-pressure steam and feed-water pip exhaust steam feed water heater and circulating water pi steam valves and feed water heaters, and feed pump. Specificat and form of tender from the borough electrical engineer (Mr. Gilbert Bell), 85, Fulham Palace-road, W. Tenders to the to clerk (Mr. H. Thompson), Town Hall, Hammersmith, London, W by 4 p.m. May 31.

STEPNEY (London) Borough Council invite tenders for 12 mont supply of ampere-hour meters, demand indicators and time switc and arc-lamp carbons. Specifications, general conditions and for

Digitized by Google

of tender from the borough electrical engineer and manager (Mr. W. C. P. Tapper). Tenders to 27, Osborn-street, London, E., by noon June 8.

DEWSBURY Corporation invite tenders (by mid-day May 30) for supply and laying of feeder cables and erection of feeder switchboards. Specifications and forms of tender from the borough electrical engineer (Mr. R. H. Campion), 93, Bradford-road, Dewsbury.

MANCHESTER Electricity Committee want tenders by 10 a.m. June 2 for 12 months' supply of carbons, dynamo brushes, incandescent lamps, insulators, cables, &c., Forms of tender from Mr. F. E. Hughes, Town Hall, Manchester.

The Penrikyber Navigation Colliery Co., PENRHIWCEIBER, R.S.O., Glam., want tenders for 12 months' supply of electrical fittings, castings, ironmongery, paints, oils, waste, &c., Forms of tender from the Secretary.

DEVONPORT Electricity Committee want tenders by noon June 8 for 12 months' supply of d.c. meters, paper-insulated cables and rubber-covered wires. Forms of tender, &c., from the Borough Electrical Engineer.

BLACKPOOL Corporation want tenders for two years' supply of arc lamp carbons. Form of tender, &c., from the Borough Electrical Engineer.

BELFAST Asylum Committee require tenders by noon June 12 for the electric lighting of two villas at Purdysburn. Specifications, &c., from the Town Clerk.

BECKENHAM Council want tenders by 4 p.m. June 12 for the wiring of houses. Forms of tender, &c., from the engineer, Electricity Works, Beckenham.

HESTON and ISLEWORTH Council require tenders by noon June 14 for supply of metallic filament lamps for street lighting. Particulars from the Engineer, Electricity Works, Hounslow.

LIVERPOOL Overhead Railway Co. want tenders by 10 a.m. June 6 for 12 months' supply of electrical fittings, insulating tapes, ironmongery, &c. Forms of tender, &c., at 31, James-street, Liverpool.

WORTHING Corporation require tenders by noon June 12 for supply and erection of two Diesel oil engines and c.c. generators. Specification, &c., from the Borough Electrical Engineer.

Tenders are invited up to July 25 for the supply of 12 sections of a branching multiple magneto lamp signalling switchboard, &c., or one automatic or semi-automatic switchboard, &c.; up to June 14 for supply of a branching multiple magneto lamp signalling switchboard at Ballarat, and a c.b. multiple switchboard to the Postmaster-General's Department, SOUTH AUSTRALIA. Tender forms, &c., from 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, MELBOURNE (Victoria), will receive tenders until 3 p.m. June 13, for the supply of electric lighting material, 12 accumulators and 400 cable distributing boxes and chemicals and glassware for batteries.

Tenders will be received at the Town Clerk's office, AUCKLAND, N.Z. until 4 p.m. of Thursday, June 15, for supply and erection of machinery for the new power station, including water-tube boilers, feed pumps, economisers, conveyor and steam pipes, and induced draught plant; d.c. steam generators, condensers, auxiliary machinery, &c. Specifications, &c., at 13, Victoria-street, London, S.W.

The Town Clerk, WANGANUI, N.Z., will receive tenders until July 12 for supply of generating plant, gas-producing plant and battery and booster for the Corporation tramways. Specification can be seen at 73, Basinghall-street, London, E.C. Local representation is necessary.

Tenders will be received at the Italian Royal Arsenals, SPEZIA and VENICE, until 11 a.m. June 2, for supply of electric cables and wires (estimated total amount £1,420). Specification (in Italian) may be seen at 73, Basinghall-street, London, E.C.

AUCKLAND (N.Z.) Harbour Board want tenders for supply of two electric motors (15 B.H.P. and 20 B.H.P.), with gear. Particulars from Messrs. W. & A. McArthur (Ltd.), 18 & 19, Silk-street, Cripplegate, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

West Ham Corporation has accepted the following tenders:—
Walter Scott (Ltd.), 500 tons steel girder rails and 13 tons steel fish-plates, £3,360, 7s. 6d.; Bayliss, Jones & Bayliss, tie bars, fish-bolts and anchor plates, £412. 16s. 8d.; Edgar Allen & Co., points and crossings and construction of layouts in cast steel, £520. 11s., ditto in manganese steel (including "leg crossings"), £1,972. 6s. 4d.; Watlington & Co., traction poles and fittings, £771. 14s. 2d.

Greenock Corporation electricity department have placed the following contracts in connection with the extension to Dellingburn power station:—
Babcock & Wilcox, water-tube boilers with chain grate stokers, and coal and ash bunkers and conveying plant; British Westinghouse Electric & Mfg. Co., one 2,000 kw. turbo-alternator, with condensing plant, and two 500 kw. rotary converters.

London County Council have accepted the following tenders:—
T. Butlin & Co. (£1,006), S. Griffith (£117) and Martin & Son (£1,591), for iron castings for the Tramways department.
Brecknell, Munro & Rogers, £76. 18s. 2d. (lowest tender), for overhead fittings for Bow and Hammersmith car-sheds. (Seven tenders received; highest £108. 16s. 10d. Chief officer's estimate £110.)

Southend Council have accepted the following tenders:—
J. T. Halsey, wiring work at the Sanatorium, £46. 15s.; E. A. MacGregor, wiring school medical examination room, £5. 3s.; J. Stone & Co., apparatus for electrically controlling points, £45; E. Allen & Co., tramway points and crossings, £267; Peckham Truck Co., special flexible truck, £125; W. Bane & Co., permanent way tie-bars, 10¼d. each.

Walthamstow Council have accepted the following tenders:—
Midland Eng. Co., natural draught cooling tower, £900, concrete tank and foundations for cooling tower, £260; Walsall Elec. Co., two switchboard panels, £247; Hurst, Nelson & Co., one spare set tramway wheels, £31. 5s.

Messrs. Ransomes & Rapier recently obtained a contract for the supply of two electric travelling cranes (to lift 20 tons on the main and 5 tons on the auxiliary lift), with motors, &c., for the Eastern Bengal State Railway workshops.

Prahran-Malvern (Victoria) Tramways Trust have placed a contract with Noyes Bros. for rails, fishplates, fastenings and bonds for the Dandenong-road line at £6,624.

Islington (London) Guardians have accepted the tender of the Private Telephone Co. for the installation of a new fire alarm system at the school, at £65. 10.

Luton Council have accepted the following tenders:—
W. H. Allen, Son & Co., condenser, £1,455; E. Green & Son, economiser, £191, and renewal of sections, £13. 15s. each.

Messrs. Siemens Bros. Dynamo Works have obtained a contract from Rochdale Tramways Committee for the supply of Tantalum traction lamps for the ensuing 12 months.

The D.P. Battery Co. have secured the contract for the new storage battery for Hindhead electricity works.

Melbourne (Australia) City Council have placed a contract with Mr. W. C. Rowe for 6,000 50 c.p. Pope metal filament lamps.

Thanet Board of Guardians have accepted the tender of R. Anderson & Co. for lightning conductors, at £33. 15s.

Essex Education Committee have accepted the tender of Joslins Limited for wiring Colchester secondary schools, at £439. 9s. 6d.

Works Driving.—Messrs. Siemens Bros. Dynamo Works have obtained an order for the electrical equivment of the new works of the Carlyle Trading & Investments Trust, at Bromley (London), E., including the supply of generators, motors, switchboards and electric lighting. The wiring has been sublet to Messrs. Walter Mossop & Co.

Oil Eliminators.—The Paterson Engineering Co. inform us they have received a repeat order from Birmingham Corporation for supply of one of their oil eliminators with quartz sand filter for the removal of all trace of oil from 350,000 lb. of condensed steam per hour with a peak load of 500,000 lb. This, with the eliminator installed at the Summer-lane generating station in 1908, will (it is claimed) constitute the largest plant of its kind in existence. The combined plant will have a capacity of 800,000 lb. per hour.

Country House Lighting.—Messrs. Semens Bros. Dynamo Works have secured an order for a country house lighting installation at Chudleigh, Devonshire, including generating plant, storage battery, switchboard and lighting. The wiring, which is being carried out with Stannos wires on the concentric system, has been sublet to Messrs. A. H. Brooking & Co., Exeter.

Yorkshire Boilers.—During the last month the Yorkshire Boiler Co. have received (amongst other contracts) orders for a 24 ft. by 8 ft. 6 in. Yorkshire boiler for Bingley, two 24 ft. by 7 ft. 6 in. for 180 lb. pressure for Edinburgh, and one 24 ft. by 9 ft. 6 in. for Leeds.
The guaranteed evaporation of the two 7 ft. 6 in. diameter boilers is 1,800 gallons per hour, and that of the 24 ft. by 9 ft. 6 in. 1,500 gallons per hour. The company are also installing two 24 ft. by 8 ft. 6 in. Yorkshire boilers in the Halifax district, and one 24 ft. by 8 ft. in Huddersfield, and have just completed the application of one 20 ft. by 9 ft. to a dye-works in Dewsbury.

Coronation Illuminations.—Messrs. Siemens Bros. Dynamo Works have obtained the contract for a complete scheme of Coronation illuminations and decorations for the Piccadilly Hotel.
In accordance with their usual custom, the firm are sub-letting the actual contracting, and in this instance the work is entrusted to Messrs. Duncan Watson & Co., of Berners-street, London, W.
Croydon Town Hall is to be illuminated electrically on Coronation Day,

Digitized by Google

at a cost of £100.—*Willesden* Council will allow consumers on the maximum demand system to have their indicator short-circuited for two consecutive nights in Coronation Week at a charge of 1s., and other consumers will be charged at 1½d. *per* unit, with an inspection fee of 2s. 6d.

Commonwealth Contracts.—The Australian Postmaster-General's Department has accepted the following tenders :—

Victoria.—Geo. Sweet, glazed earthenware conduits; Richd. Taylor, cement concrete conduits; J. A. Newton & Co., open circuit condenser telephones; Western Electric Co., Lawrence & Hanson and Chappel & Nichols, telephone apparatus and material.

New South Wales.—Western Electric Co., apparatus for William-street, Sydney, telephone exchange (£780) and for Mosman exchange (£620); additional apparatus and material for Petersham exchange (£912) and for Edgecliffe exchange (£905); Federal Potteries (Brunswick, Victoria), 57,500 lineal ft. of ducts.

Queensland.—India Rubber, Gutta Percha & Telegraph Works Co., Wheatstone bridge and rheostats; R. W. Paul, two galvanometers; J. Campbell & Sons, split pipes; and Gell Telegraphic Appliances, two Gell perforators.

Western Australia.—General Electric Co., tinned copper, rubber-insulated cotton-covered taped and braided wire; Western Electric Co., W. T. Henley's Telegraph Works Co., J. Bartram & Sons and Mills & Co., telephone apparatus and material.

BUSINESS NOTICES.

Messrs. Siemens Bros. Dynamo Works (Ltd.) have removed their Calcutta office from 12, Dalhousie-square, to Clive-buildings, Clive-street.

The Rees Roturbo Mfg. Co. have opened a branch office at Norfolk House, Victoria Embankment, London, W.C. Telegrams: "Hydroturbo London"; telephone: City 9156.

Messrs. W. T. Henley's Telegraph Works Co., who have hitherto been represented in India by agents, have recently opened an Indian branch office at 13-1, Clive-row, Calcutta, and Mr. C. H. R. Thorn has been appointed manager of the Company in India. Messrs. Greaves, Cotton & Co., Bombay, and the Russe Engineering Works (Ltd.), Calcutta, will continue to stock the Company's wires and cables.

Messrs. S. A. Sillem, F. A. Donnison and W. Sillem having transferred their interests in the Phœnix Electric Heating Co., electric cooking and heating apparatus manufacturers, 17, Morwell-street, Tottenham Court-road, London, W.C., to Mr. S. Douglas Cox, who has held the position of manager to the Company for the past three years, Mr. Cox will continue to conduct the business at the same address, under the existing title.

Gilbert A. Beckett and Chas. C. Aronsberg, electricians, &c., 57A, Renshaw-street, Liverpool, have dissolved partnership. Debts by Mr. Aronsberg.

Patent Development.—The proprietor of Letters Patent No. 11,154 1909, relating to "Batteries and Battery Holders," desires to dispose of same or to grant licences, with a view to the adequate working of the patent in this country. Inquiries to Messrs. Cruikshank and Fairweather (Ltd.), 65-66, Chancery-lane, London, W.C.

The proprietors of British Letters Patent No. 13,228 1905, relating to "Telephone Transmitters," and No. 13,311 1905, relating to "A telephonic dictating machine," desire to license British manufacturers to work same in this country. Applications to Messrs. Boult, Wade & Tennant, Chartered Patent Agents, 111 and 112, Hatton-garden, London, E.C.

The proprietors of patent No. 4461/08 for "Improved Process of and means for Manufacturing Filaments for Illuminating and Heating Purposes" also desire to enter into arrangements for exploiting same in this country. Applications to Messrs. Haseltine, Lake & Co., 7 & 8, Southampton-buildings, Chancery-lane, W.C.

The proprietor of patent No. 10,580/1900, for "Improvements in electric furnaces of great power," desires to enter into arrangements by way of licence or otherwise for exploiting same in this country. Further particulars from Messrs. Gedge & Feeny, 60, Queen Victoria-street, London, E.C.

Swedish Chamber of Commerce Year-Book.—We have received from the Swedish Chamber of Commerce in London (5, Lloyd's-avenue, E.C.) a copy of the Chamber's year-book for 1910, which contains much useful information and interesting statistics, trade reports, charts, &c., relating to trade and commerce between Great Britain and Sweden.

The work contains, in addition to the fourth annual general report of the Chamber and the transactions of the year, a list of members of the Chamber, names and addresses of Swedish traders' representatives in Great Britain and Ireland, reports on the iron, steel, timber, paper and glass trades, &c. There is also a large sheet giving particulars of the imports into the United Kingdom of articles partly supplied by Sweden.

BANKRUPTCIES, LIQUIDATIONS, &c.

The examination of Alphonse Christian Wampach, electrical engineer, Formby Lodge, Seabrook-road, Hythe, took place on Saturday. Liabilities £1,392; deficiency £1,342.

A dividend is to be paid to creditors of Tasker, Sons & Co. (Ltd.) and claims are to be sent by June 14 to Mr. G. S. Greening, 18, Norfolk-row, Sheffield, or Mr. T. G. Shuttleworth, Royal Insurance-buildings, Church-street, Sheffield.

A first and final dividend of 2s. 6¼d. will be payable on May 30 at 30, Mosley-street, Newcastle-on-Tyne, to creditors of Edward Surtees, electrician, 22, King-street, South Shields.

Herr Rudolf Busch, 5A, Lindenstrasse, Cöpenick, has been appointed trustee in the bankruptcy of Conrad Felsing, jun., cable machinery maker, Cöpenick, near Berlin.

The Australian Electrical Co. (Ltd.) is being wound up voluntarily. Mr. E. Pears, 20, Copthall-avenue, London, E.C., is liquidator. Meeting of creditors at 20, Copthall-avenue on May 29.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*NOTE.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

March 20, 1911.

6,905 ATKIN. Electrically-controlled presses and the like.
6,961 SHEARS. Track brakes for tramway and like vehicles
6,983 BARNES. Luc joints for the lids of electric accumularot boxes.*
6,984. 6,986 OLIVER ARC LAMP (LTD.), OLIVER & PELL. Flame arc lamps or the like.
6,988 B.T.-H. CO. & NEEDHAM. Electric lamps.

March 21, 1911.

6,996 EDWARDS & STAIT. Electric tramways motor-controller, back run electric brake.
7,021 RAILING & BARTLETT. Cooling the commutators and brushes of dynamo-electric machines.*
7,045 FRIED. KRUPP AKT.-GES. Continuous electric current generators with separate excitation. (Convention date, 18 5 10.)*
7,061 AKT.-GES. BROWN, BOVERI ET CIE. Variable frequency commutator machines. (Convention date, 11 4 10, Germany.)*
7,067 TOUSEY. X-ray tubes.*
7,086 HARDY & HUNGERBUHLER. Separators for secondary batteries.*
7,092 JOHNSON & PHILLIPS & BROCKIE. Devices for suspending, lowering and hoisting electric and other lamps.
7,097 SCHULTZ. Switches and interrupters for electric circuits.
7,103 B.T.-H. CO. (G.E. Co., U.S.) Boron compounds and methods of producing the same.*
7,104 B.T.-H. CO. (G.E. Co., U.S.) Electric switches.

March 22, 1911.

7,161 WATERHOUSE. Electric lampholders.
7,198 MUNRO & RAIL-LESS ELECTRIC TRACTION CO. Trolley bases for electric traction systems. (Divided application on 11,157 5 5 10.)
7,220 FUSS. Electrical potential regulators. (Convention date, 22 3 10, Germany.)*

March 23, 1911.

7,235 TAINTON & PRING. Electro-deposition and refining of zinc.
7,266 GLEAVES & HOLLIDAY. Electric tramcars.
7,295 OZONAIR (LTD.) & JOSEPH. Transforming continuous currents into alternating currents.*
7,306 CURTIS. Electric lamps.
7,307 READ. Electric lamps.
7,320 B.T.-H. CO. (A.E.G., Germany.) Resistances for regulating induction motors.

March 24, 1911.

7,341 FAIRLESS & PRENTICE. Adjustable carrier for gas or electric light reflectors, shades, globes and the like.
7,373 BIRKETT & THORNTON. Electric switch of rotatory type for electric light or power purposes.
7,376 LEE GUINESS. Magneto trip mechanism for internal combustion engines.
7,386 ROUSE. Thermo-electric motor.
7,395 DICKSON. Arc lamps.
7,416 SCHRODER. Time switches for electric lighting. (Convention date, 23 5 10, Germany.)*

March 25, 1911.

7,501 SIEMENS-SCHUCKERTWERKE G.M.B.H. Arc lamps. (Convention date, 26 3 10, Germany.)*
7,504 FULLER & FULLER. Electric condensers.
7,511 KRANNICHFELDT. Device for insulating the twisted ends of electric wires.*
7,519 MARCONI'S WIRELESS TELEGRAPH CO. & ROUND. Receivers for wireless telegraphy.
7,522 HILL. Electric meters and the like.

March 27, 1911.

7,568 MEREDITH. Sparking plug.
7,569 FRISBY. Current detectors.
7,579 MURRAY. Synchronising arrangement for a multiplex printing telegraph system.
7,582 WALKER. Spark generator for wireless telegraphy.
7,611 CLEMENT. Telephone exchange systems.*
7,631 SIEMENS BROS. DYNAMO WORKS. (Siemens-Schuckertwerke G.m.b.H., Germany.) Braking polyphase series motors.*
7,635 LEVY & GEORGE. Circuit breaker.
7,645 BONAPARTE. Safety interrupter.
7,668 ALLGEMEINE ELEKTRICITATS-GES. Voltage regulators. (Convention date, 26 3 10, Germany.)*
7,669 B.T.-H. CO. (Allgemeine Elektricitäts-Ges., Germany.) Meters.
7,675 GENN. Terminals or connectors.

March 28, 1911.

7,697 PURLE. Electrically-produced heat for domestic and other purposes.
7,705 TAYLOR. Changing the frequency of alternating currents
7,731 DELL & SON & RICHARDS & STEWART. Reversing mechanism for metal-planing machines.
7,736 SCHATTNER. Rheostats.*
7,749 BALSILLIE. High frequency electric currents.
7,764 SIMPSON. Electric energy and apparatus therefor.
7,770 B.T.-H. CO. (G.E. Co., U.S.) Indicating apparatus for magnetic compasses and the like.

Digitized by Google

March 29, 1911.

7,785 HOLMES & HOLMES. Controlling electric motors.
7,803 LAUDER. Lamp lock and shade holder for incandescent electric lamps.
7,852 SIEMENS BROS. & Co. (Siemens & Halske Akt.-Ges., Germany.) Telephone exchange circuits.*
7,962 H. ARON ELEKTRICITATSZAHLER-FABRIK G.M.B.H. Electrical clock. (Convention date, 7/1/11, Germany.)*
7,966 BARROLLIER. Machines for making the joint between the filament support and the lamp bulb in incandescent electric lamps. (Convention date, 29/3/10, France.)*
7,972 JOHNSON. Continuous electric switch.*
7,976, 7,977 & 7,978 FALES. Telephone systems. (Divided Application on 1,422/10, 19/1.)*
7,982 ELLSON. Reversing mechanism for electrically-driven machine tools.
7,996 B.T.-H. Co. (Allgemeine Elektricitats-Ges., Germany.) Time relays.

Maroh 30, 1911.

7,921 SPRUCE. Controller for stopping power machines in case of accident or emergency.
8,004 SCHWAB. Incandescing bodies for electric lamps. (Convention date, 9/4/10, Germany.)*
8,018 SCHUER & HADDRELL. Flame arc lamps.
8,022 MONNOT. Electric heaters. (Convention date, 1/4/10, France.)*
8,032 STRELOW. Meters. (Addition to 21,240/10. Convention date, 30/3/10, Germany.)*
8,033 STRELOW. Measuring instruments. (Convention date, 30/3/10, Germany.)*
8,039 H. T. W. BOWELL & G. B. BOWELL. Electric clocks.
8,044 ROGERS. Alarm signal.

March 31, 1911.

8,063 WRIGHT & BURNSIDE. Contact breakers.
8,082 KOCHS. Separation of liquids by electrical treatment.
8,103 OERTEL. Arc lamps.*
8,149 ALEXANDERSON. Control of alternating current electric motors. (Convention date, 2/4/10, United States.)*
8,150 ALLGEMEINE ELEKTRICITATS-GES. Regulators. (Convention date, 1/4/10, Germany.)*
8,151 RENNERT. Regulating devices for furnace-dampers, valves, and the like. (Convention date, 1/4/10, Germany.)*

April 1, 1911.

8,226 MORRIS & LISTER. Switches, circuit-breakers and the like.
8,234 BLOXAM. (Robert Bosch, Firm of, Germany.) Carbon-holder for distributors of electrical ignition machines.*
8,235 BLACKALL & JACOBS. Operating railway block telegraph indicators.*
8,236 BULL, ARNESEN & SIZER. Wireless telegraphy.
8,238 B.T.-H. Co. & WISE. Controllers for electric motors.

April 3, 1911.

8,275 OSMIVE & ADAMS WATKIN Co. Resistances and controlling devices.
8,293 CROOK. Selective electric sigalling over a number of conductors.*
8,340 LINDOE. Magneto-electric machine.

April 4, 1911.

8,359 BODDAM. Hydraulically-balanced electric lifts.
8,375 HIRST & CHAPMAN. Wall plugs and sockets.
8,387 OELSCHMIDT. Method of and means for receiving electric waves. (Convention dated 4/4/10, Germany.)*
8,392 SIEMENS BROS. DYNAMO WORKS & KOETTGEN. Ventilation of dynamo-electric machines.*
8,400 HUBT & HURT. Sparking plugs.

SPECIFICATIONS PUBLISHED.

1909 SPECIFICATIONS.

3,702 MARINO. Separators for use in electrical batteries and electrolytic apparatus. (Cognate Application, 4,398/10.)

1910 SPECIFICATIONS.

3,863 HOPE. Fusible cut-outs for controlling electric circuits. (Cognate application, 15,662/10.)
3,930 FIELD & FERRANTI. Electric circuit-breakers and the like.
[illegible] McGINNESS. Trolley-head collectors.
[illegible] ADAMS MFG. CO. (Cutler Hammer Mfg. Co.) Controllers for alternating current motors.
[illegible] ADAMS MFG. CO. (Cutler Hammer Mfg. Co.) Pressure-regulating devices.
[illegible] EDNER & HOLMSTROM. Cooling devices for telephone transmitters. (3/4/09.)
[illegible] NEUHOLD. Telephone systems. (20/4/09.)
[illegible] CONRADI & CONRADI. Fusible cut-outs.
[illegible] BARRY & CLARKE. Rheostats.
[illegible] GERVENKA. Incandescence filament or body and process for manufacturing the same. (23/10/09.)
[illegible] ...KER. Switches.
[illegible] ...LLIS. Electric incandescent lamp holders.
[illegible] ADAMS MFG. CO. (Cutler-Hammer Mfg. Co.) Means for starting and controlling electric motors.
[illegible] RANKIN. Electric controlling and regulating apparatus.
[illegible] ELECTRIC CO. & SANDY. Cells or cases for electric batteries.
[illegible] REINHART. Holders for electric incandescent lamps.
[illegible] BALDWIN. Sound-reproducing devices of the telephone receiver type.
[illegible] HARRISON. Exhaustion of incandescent electric lamps.
[illegible] & BRITISH EVER-READY ELECTRICAL CO. Holders or fittings for electric incandescent lamps.
[illegible] STEVEN. Electric condensers. (12/5/09.)
[illegible] ROUSE. Time signalling apparatus.
[illegible] PARKER, CHAPMAN & CO. & HARRIS. Resistances.
[illegible] EDNER & PEEL-CONNER TELEPHONE WORKS. Coating electric cables.
[illegible] B.T.-H. Co. (G.E. Co., U.S.) Leading-in conductors for electric lamps and other similar devices.
[illegible] LAKE (Weston Electrical Instrument Co.) Synchronising alternating current apparatus.
[illegible] SIEMENS BROS. & Co. & DIEBELHORST. Conductors.
[illegible] EMEL. Electrical contact device. (Addition to 6,765/08. Convention date not granted.)
[illegible] ...ERY. Electric furnaces. (1/9/09.)
[illegible] FRITCHETT. Accumulator boxes.
[illegible] MOSE. Electrical switches operated by a vehicle passing along a railway.
[illegible] ANDERSON, RUSSELL & GRAY. Systems for the distribution of electric energy. (Addition to 21,219/09.)
[illegible] SWAFY. Manufacture of electric metal filament lamps. (6/12/09.)
[illegible] HANNEMANN. Primary galvanic batteries.
[illegible] ADAMS MFG. CO. (Cutler-Hammer Mfg. Co.) Motor controller circuits.
[illegible] SIEMENS BROS. DYNAMO WORKS. (Siemens Schuckertwerke Ges.) Contro devices for electric cars on routes in which two different voltages are supplied.
[illegible] BURNLEY & BELL. Telephone systems.
[illegible] FAIRWEATHER. (Hart Mfg. Co.) Electric switches.
[illegible] SYNDICAT (Ges. fur Drahtlose Telegraphie.) Arrangement for producing but slightly damped electrical oscillations.
[illegible] KOHNE & KAHLE. Inverted lamps.
[illegible] SIEMENS & HALSKE AKT.-GES. Manufacture of metallic filament incandescent lamps. (9/6/10.)
[illegible] BLOXAM & SEIDEL. Electro-magnetic clutches. (14/2/10.)
[illegible] BLOXAM & SEIDEL. Electromagnetic clutches. (25/7/10, addition to 19,786/10.)
[illegible] SIEMENS BROS. DYNAMO WORKS. (Siemens Schuckertwerke Ges.) Cooling transformers for electric machines. (Patent of addition not granted.)
[illegible] SIEMENS BROS. & Co. (Siemens & Halske Akt.-Ges.) Circuits for telephone exchanges.
21,310 SIEMENS BROS. DYNAMO WORKS, BOLTON & WILLCOCKS. Electric switches for high-tension currents.
21,583 SIEMENS BROS. DYNAMO WORKS. (Siemens-Schuckertwerke Ges.) Rotary field electric transformers.
22,410 FAIRWEATHER. (Stein.) Sub-station telephone.
22,411 FAIRWEATHER. (Stein.) Telephone system.
23,121 SCHROTER. Manufacture of metal filament electric lamps. (19/1/10.)
23,535 ATWOOD. Incandescent electric lamps. (3/1/10.)
23,577 MACQUAIRE. Sparking plugs. (30/10/09.)
23,958 MILCH. Control of alternating current induction motors.
24,122 WESTERN ELECTRIC CO. (E. Zwietusch & Co.) Protective covering for flexible electric conductors.
24,286 KRAUSS & MASCHINEN-FABRIK UND MUHLENBAUANSTALT G. LUTHER AKT.-GES. Magnetic separators.
24,549 SKAUPY. Incandescent metal filament lamps. (13/7/10.)
24,668 CAMBRIDGE SCIENTIFIC INSTRUMENT CO. & DARWIN. Thermo-electric circuits.
25,179 MANNY & BINZEL. Selective-signalling devices.
25,280 GOLDTHORP. Receiving apparatus for wireless telegraphy. (29/10/09.)
26,568 WILDERMAN. Electrolytic cells for the electrolysis of alkaline salts. (22/12/09.).
26,959 HESSELN. Two-fluid galvanic cells. (11/2/10.)
27,448 ROBERTSON. Device for carrying electric cables, conduits, rods or the like.
28,057 AMERICAN AUTOMATIC TELEPHONE CO. & GOODRUM. Electric switches. (Divided application, on 29,963/09, Dec. 22.)
28,356 SIEMENS SCHUCKWERTWERKE GES. Electric searchlights. (26/1/10. Addition to 12,556/08.)
28,396 GOTTSCHALK. Telephonic instruments.
28,397 GOTTSCHALK. Guards for telephone transmitters.
28,552 PAILLET, DUCRETET & ROGER. Discharging electricity from textile and other materials during manufacture.
29,593 MACDONALD. Electric motors.
29,654 DICKER. (Automatic Electric Co.) Electrical impulse transmitting or calling devices for telephone systems. (Divided application on 1,298/10, Jan. 18.)
29,927 BECK. Telemeters. (30/12/09.)
29,941 KUNKEL. Dynamo electric machines. (29/12/09.)
30,313 EVERSHED & VIGNOLES, LTD. Hand spikes for making electrical connections.

1911 SPECIFICATIONS.

252 B.T.-H. Co. (G.E. Co.). Resistance units.
513 CARL ZEISS (FIRM OF). Telemeters. (17/1/10.)
847 LUNDBERG, LUNDBERG & LUNDBERG. Plug and socket connections for electric light and power purposes.
950 SIEMENS BROS. DYNAMO WORKS & LAUGHTON. Shade carriers for electric, gas or other lamps.
2,014 SIEMENS & HALSKE AKT.-GES. Electric transmission of signals comprising combined numerals. (9/2/10.)
2,017 BOULT. (Smith.) Secondary or storage batteries.

COMPANIES' MEETINGS AND REPORTS.

ANGLO-PORTUGUESE TELEPHONE CO. (LTD.)—The directors' report for 1910 states that the gross revenue was £54,391, of which operating, management and general expenses absorbed £31,222 and royalties to the Portuguese Government £1,553, leaving a gross profit of £21,614. After providing for debenture interest (£2,316), sinking fund (£1,283), income tax (£684) and appropriating £10,000 to reserve (which now amounts to £37,000), the amount available, including £5,392 brought forward, is £12,722. In December an interim dividend of 3 per cent. (£3,000) was paid, and the directors now recommend a final dividend of 5 per cent. (tax free), making a total distribution of 8 per cent. for the year, leaving a balance of £4,722 to be carried forward.

ELECTRIC SUPPLY CORPN. (LTD.)—Mr. J. G. B. Stone, who presided at the meeting on Monday, said the lamp connections had increased from 113,699 to 135,719 8-c.p., a satisfactory increase of 19 per cent., to which Dumbarton was the largest contributor. The lamp connections at Hendon at the beginning of the present month had increased to 44,644 8-c.p., with 4,400 awaiting connection. There was a small decrease in the total number of units supplied, although their revenue had increased. The decrease was due to the reduction in the supply to the tramway company at Dumbarton and to the strike of the shipbuilding employés in that district. In spite of a shrinkage in output from those causes they had an increase in gross revenue of £1,665 and of £1,924 in profit. They thought the shareholders would receive some dividend this year. They did not like to commit themselves to what it would be, but they hoped it would be somewhere in the neighbourhood of 3 per cent.

KALGOORLIE ELECTRIC POWER & LIGHTING CORPN. (LTD.)—The directors' report for 1910 states that, although the plant was only lightly loaded for the first eight months, largely owing to the fire at the Great Boulder Perseverance mine, the profits in Kalgoorlie show an increase over those for 1909. The additions made to plant and machinery during the year include new boilers and condensing apparatus, as well as the new engine and alternator referred to as the new unit in last year's report. On March 31 the tramway company exercised their option under the contracts with this company to pay the existing price for a further term of five years.

LISBON ELECTRIC TRAMWAYS (LTD.)—The chairman (Mr. L. Breitmeyer) stated at the meeting on Wednesday that the company had more than maintained its successful position during 1910. They had carried 49,925,167 passengers, earning £328,599. 14s. 2d., against 47,995,076 passengers and £301,426. 15s. 3d. for 1909, leaving a net profit of £132,980, against £129,351. 1s. 9d. in the preceding year. Those figures would have been considerably increased had not the revolution, which broke out in Lisbon in October last, disorganised the business life of the city, and in fact the tramway operations were entirely suspended for three days, and some considerable time elapsed before the entire traffic on all lines was completely re-established. Mr. Rommel and himself went to Lisbon immediately after the overthrow of the Monarchy, and they remained there for some time, interviewing the principal officials of the Provisional Government and of the municipality, &c. They considered all complaints and made many concessions, but all their endeavours failed to avert a strike, which took place some time after their return to London. Under the peculiar circumstances, the directors thought the wisest course to adopt would be to request Senhor Almeida, the Minister of the In-

Digitized by Google

terior, to act as arbitrator, and the result of his arbitration and the determination of his award were successful in putting an end to the strike. The company, however, was obliged to make great sacrifices, both as regards reduction of working hours, increase of wages and the granting of holidays with pay, and as a consequence their operating expenditure would be considerably increased, while they could hardly expect for some time to come that the rate of expansion of traffic would be resumed on the scale obtaining before the revolution. Therefore, the board deemed it prudent to limit the final dividend to 2½ per cent., making a total of 5½ per cent. for the year. The tramways had sustained no damage whatever, and, bar the suspension of traffic, no injury had been done to their undertaking. The tramways were now in full working order. The equipment, rolling stock, permanent way, &c., were in excellent condition, and their employés had lately shown a spirit of loyalty, when a general strike of workers was attempted, which proved that their concessions to them had not been made in vain. They were still at issue with the Lisbon municipality in the interpretation of the contracts between the company and that body. The unreasonable demands made upon the company had left the board no alternative but resistance through the law courts. The directors would let no opportunity slip of coming to a friendly understanding with the municipality, and, in fact, negotiations were still being carried on to that end.

PEASE & PARTNERS (LTD.)—The directors' report states that an agreement has been entered into with the Newcastle-on-Tyne Electric Supply Co. to put down a power generating station to use the spare heat and gas from coke ovens at Bowden for generating electrical energy. An arrangement had also been entered into with the Newcastle Company and their allied companies in Durham and Cleveland for the supply of electrical power at reasonable rates to all the company's other collieries, mines and works as required.

POTTERIES ELECTRIC TRACTION CO. (LTD.)—The capital expended during 1910 amounted to £1,784. 12s. 4d. The total receipts were £110,489. 17s. 11d. The traffic receipts (£92,349. 19s. 8d.) showed an increase of £418. 5s. 7d., and the return on the investment in the North Staffordshire Tramways Co. an increase of £1,156. 14s., consequent on the declaration of a bonus of 2s. per share on the ordinary shares. Working expenses increased by £2,320. 10s., of which £1,089. 16s. 8d. was for permanent way. Deducting expenses and adding amount forward the balance was £27,384. 16s. 5d. The directors recommend that £2,302 10s. be placed to reserve, £7,525. 9s. to renewals account, and that after paying preference dividend (£12,250), a dividend be declared of 2 per cent. on the ordinary shares (£4, [illegible] 495. 17s 5d. being carried forward. During the year the Board of Trade released the Company from its obligations to construct certain authorised extensions in the outlying districts of the Potteries.

RANGOON ELECTRIC TRAMWAY & SUPPLY CO. (LTD.)—At the meeting last week the chairman (Mr. F. Tobin) stated that they had issued £22,000 debenture stock to meet the cost of the new power house, &c. The directors had placed £7,500 to reserve for renewals. The tramway receipts continued to increase, while in the supply of electricity for public lighting and power there was distinct progress.

REUIER'S TELEGRAM CO. (LTD.)—The chairman (Hon. Mark F. Napier) stated at the meeting on Wednesday that the utmost care would be taken in the development of their new banking branch, the progress of which, so far, had given every prospect of eventual success. As a result of last year's operations they had been able to add a substantial sum to the general and telegraphic remittance reserves, which had been combined. With regard to the equalisation of dividends, he pointed out that, although they had done very good business of recent years, the uncertainty of affairs all over the world had taught them to provide for a possible rainy day. They had not had many in recent years, but he remembered the time when the company had to meet very strong competition. The difference in the cost of transmitting messages was a matter they had to provide against.

TRACTION & POWER SECURITIES CO. (LTD.)—The directors' report for 1910 states that there is a credit balance of £26,482, which, added to £5,623 forward, gives £32,105. The directors have applied £1,920 to writing down certain securities and transferred £25,000 to investment account, leaving £5,185 to be carried forward. The Clyde Valley Electrical Power Co. continues to make good progress. The gross revenue and profit for 1910 much exceed those of any previous year. The earnings of the Mersey Railway Co. again showed an increase. The engagements of the Société Electrique Westinghouse de Russie, in connection with the contract guaranteed by the company, have been fully met.

URBAN ELECTRIC SUPPLY CO. (LTD.)—The gross profits for 1910 amount to £47,268. 10s. 9d., and, after deducting London expenses, the balance is £44,911. 16s. 8d. The profit balance is £30,971. 11s. 11d., which falls short by £1,528. 8s. 1d. of the amount (£32,500) required to meet the 5 per cent. guaranteed dividends on the capital. This deficit has been provided by Edmundsons' Electricity Corpn. under their contract. Provision has also been made of £2,221. 5s. 6d. depreciation of plant and machinery. The profits for 1910 exceed by £33,192. 17s. 5d. the amount of £12,107. 0s. 6d. required to meet debenture interest. In view of the expiry on Dec. 31 last of the contract under which the dividends have hitherto been guaranteed, of the necessity for increasing the provision for depreciation, and of the fact that the debt owing to the contractors is now bearing interest, the directors have decided to defer any declaration of dividend for the current year until the accounts for the year are available. The equivalent of 525,160 33-watt lamps were connected to the mains of the various undertakings at Dec. 31 last, against 476,596 in 1909 and 437,503 in 1908.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES, &c,

NEW COMPANIES.

ELECTRIC BLEACHERS (LTD.) (115,837.)—Reg. May 18, capital £100 in £1 shares, to acquire and turn to account patent No. 1,941 of 1911, and to carry on the business of manufacturers of apparatus used in connection with bleaching. Private company. Reg. office: 39, Victoria-street, Westminster.

MANSELL (LTD.) (115,871.)—Reg. May 17, capital £500 in £1 shares (450 7 per cent. cumulative preference and participating and 50 founders'), to take over the business of electricians, electrical and mechanical engineers and contractors, &c. Private company. Reg. office: 13, Cecil-court, Charing-cross, London, W.C.

SCANDINAVIAN FOIL CO. (LTD.) (115,831.)—Reg. May 17, capital £20,000 in £1 shares, to acquire any patents in Norway or Sweden and elsewhere, to carry on the business of manufacturers of and dealers in aluminium and aluminium foil, and to adopt an agreement with the International Foil Co. First directors: S. O. Larsen, J. E. Vik, O. Roakvam, W. C. James, E. Ames, A. P. Sinnett and A. J. Faulding.

SHACKLETON'S (LTD.) (115,880.)—Reg. May 17, capital £2,000 in £1 shares, to carry on the business of manufacturers of and dealers in bricks, tiles, pipes, pottery and earthenware, &c., to acquire the business carried on by C. W. Shackleton as the Polesworth Electrical Appliances Co. Private company. C. W. Shackleton is first managing director. Reg. office: 47, Temple-row, Birmingham.

STATUTORY RETURNS.

BUDE ELECTRIC SUPPLY CO. (LTD.)—Return to April 29 gives capital as £7,000 in £1 shares. All shares taken up. £7,000 paid. Mortgages and charges, £2,500 mortgage debentures.

CAMBRIDGE ELECTRIC TRAMWAYS SYND. (LTD.)—In return to Feb. 22 capital is £5,000 in £10 shares. 107 shares taken up. £9. 0s. 4½d. per share called up on 90 shares, £10 per share on 10 and nil on 7. £911. 12s. 1d. paid. Mortgages and charges, nil.

MORTGAGES AND CHARGES.

BRITISH DIATORIC MFG. CO. (LTD.)—Particulars of £4,000 debentures, created as to £2,000 on June 25, 1908, and as to £2,000 on April 25, 1911, have been filed, amount of present issue being £2,000. Property charged: Company's property, present and future, including uncalled capital. No trustees.

LANCASHIRE DYNAMO & MOTOR CO. (LTD.)—Issue on May 8 of £5,600 debentures, part of a series of which particulars have already been filed.

RECEIVERSHIPS.

ELECTRICAL FITTINGS CO. (LTD.)—W. K. Sutton, of Driffold, Mayfield-road, Moseley, ceased to act as receiver or manager on March 31.

FERABIN LAMP & ELECTRICAL ACCESSORIES (LTD.)—Notice of the appointment of G. E. Corfield, 119, Finsbury-pavement, E.C., as receiver and manager, on May 12, under powers contained in debenture dated Nov. 23, 1910, has been filed.

JAMES SCOTT (LTD.)—Notice of the appointment of H. Beswick, 7, Sweeting-street, Liverpool, as receiver and manager, by order of Court dated May 6, has been filed.

CITY NOTES.

MEMORANDA (May 25).—**Bank rate 3 per cent.** (March 9, 1911). **Price of silver,** 24⅛d. per oz. **Consols** 81⅛—81⅛ for money and for account. **Consols Pay Day, June 1; Stock and Shares Continuation Days, May 29 and June 13; Ticket Days, May 30 and June 14; Pay Days May 31 and June 15; Mining Shares Carry Over Day, May 26.**

PRICES OF METALS (London).—*Copper*, cash, 54⅞; three months 55⅛. *Lead*, English, 13¼—13⅜; foreign, 13⅛—13⅛. *Spelter*, 24¼—24¾. *Tin*, English, 196—197; foreign, 203¼ cash, 189¾ three months. *Iron*, Cleveland, cash, 46/11, three months, 47/7.

ANGLO-ARGENTINE TRAMWAYS CO. (LTD.)—Mr. T. Frame Thomson has been appointed deputy-chairman of this company.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have been asked to appoint special settling days in and grant quotations to fully and partly (50 per cent.) paid scrip for £385,000 4½ per cent. preference stock of the *Central London Railway Co.*, and a further issue of 20,000 £10 fully and partly (£4) paid shares of the *City of Santos Improvements Co.*; and also to grant quotations to $1,847,000 additional consolidated mortgage 5 per cent. 50-year coupon bonds of the *Havana Electric Railway Co.*, a further issue of £27,000 4½ per cent. first mortgage prior lien gold bonds of the *Montreal Water & Power Co.*, and partly paid scrip for £200,000 5 per cent. first mortgage debentures of the *Rhondda Tramways Co.*

UXBRIDGE & DISTRICT ELECTRIC SUPPLY CO. (LTD.)—This company is making an issue of £75,000 5 per cent. first mortgage debenture stock at par. The issue is guaranteed by Callender's Cable & Construction Co.

WINNIPEG ELECTRIC RAILWAY CO.—The directors have declared a quarterly dividend at the rate of 12 per cent. per annum.

NOTES.

Electric Lamps for Miners.

It has long been realised that a good electric lamp for use by miners would be ideal from the safety point of view, but there have been so many difficulties to be overcome in detail before attaining a really satisfactory result that the electric miner's lamp has not yet made any great headway. The want of such a lamp is felt more than ever at the present time, and is emphasised by an important announcement by the HOME SECRETARY, to the effect that a colliery proprietor has placed £1,000 at his disposal as a prize for the best electric lamp or lamps fulfilling certain specified requirements. These our readers will find set out in another column, and they are mostly of a very reasonable, and indeed essential, character. The only stipulation that we feel is open to serious criticism is that a lamp must give not less than 2 c.p. continuously for ten hours. This is a much larger candle-power than is usual with ordinary miners' lamps. In itself, of course, there is no objection to the increase in light, as it may assist the miner in his work, and there would be no difficulty in producing such a light for the time stipulated but for the fact that a miner's lamp to be of practical value must have its weight kept below quite a low figure. On this account we fear this stipulation may result in a lamp which, technically, fulfils the specified requirements, but which, nevertheless, will be impractical from the miner's point of view. In any case, however, we hope that designers and manufacturers will take up the challenge seriously. They will doubtless be encouraged to do so by the fact that, in his report on the Pretoria pit disaster, issued this week by the Home Office, Mr. R. A. S. REDMAYNE, H.M. Chief Inspector of Mines, suggests that serious consideration should be given to the possibility of replacing the gauze lamp in fiery mines by the electric lamp.

The Pretoria Pit Disaster.

THE report to which we have just referred is an effective answer to the ill-considered and reckless statements that have been made by some of the miners' representatives as to electricity being responsible for the disaster at Hulton Colliery last December. Mr. REDMAYNE, after holding an exhaustive inquiry into the circumstances of the explosion, is perfectly satisfied that the use of electricity in the mine had no bearing whatever on the disaster. This official pronouncement will be welcomed by electrical engineers, and we are sure it will do much to allay any fears that may have arisen in the minds of colliery managers as to the desirability of extending the use of electrical apparatus. It will certainly do much to strengthen the hands of managers in resisting the demands of the miners to have electrical apparatus removed from the pits. This opposition of labour to improved methods of working is to be regretted, but it will doubtless disappear as the number of mines using electrical apparatus increases.

"The National."

FOR a moribund institution the National Telephone Co. is "dying hard." There was no dullness or dolefulness about the huge gathering of the staff of the Company assembled at the Hotel Cecil on Thursday last week, to celebrate the seventeenth Annual Staff Dinner. These gatherings

Digitized by Google

have always been notable for expressions of loyalty to and zeal for the National Co.'s interests, and for the recognition that the directors have rendered to the staff on this account. But at this concluding family gathering there was a friendliness and a warmth in the proceeding throughout that must have been comforting to those who are called upon to part company after so many years of true camaraderie. The severance, if such it may be termed, was certainly softened by the kindly words of the President and by the sincere and hopeful words of the Postmaster-General, whose fine speech and graceful references to the merits of the men who are shortly "going over," were received with what was clearly the utmost respect. The remarks of Mr. SAMUEL, we are sure, conveyed to the hearts of his audience a feeling of relief which, so far as they touched upon some of the chief points at issue, could be felt, and there is to-day a hopefulness in telephone ranks that has hitherto been noticeably absent. The rank and file of the National Company, we are sure, give a large meed of credit for this to the directors and chief officials of the Company. The annual dinners, now, alas, terminated, have furnished the opportunity for cordial intercommunication between the scattered elements of this great undertaking, and will be remembered with feelings of great pleasure. We must be satisfied here with our expression of pleasure tempered with regret, and refer our readers to the full report of the proceedings which is given on a subsequent page, taking the occasion to compliment the Postmaster-General upon the manner in which he responded to a great opportunity. It must be remembered that nearly 18,000 men and women are directly interested in his statement.

The Heating of Cables with Current.

OWING to the absence of the president and vice-presidents, it fell to Dr. R. T. GLAZEBROOK to preside at the meeting of the Institution of Electrical Engineers last week. The fact that the Paper under discussion was by two members of the Staff of the National Physical Laboratory, and dealt with a valuable series of investigations carried out at Bushy House, rendered his presence in the chair particularly appropriate. This research was undertaken, it will be remembered, at the request of the Wiring Rules Committee of the Institution, and the Table of limiting currents in the new edition of the Rules has been based on the results detailed by Messrs. S. W. MELSOM and H. C. BOOTH in their Paper. In view of the criticism that has been raised in certain quarters as to the supposed excessive current density allowed in the case of small conductors, Mr. C. P. SPARKS, Chairman of the Wiring Rules Committee, showed at the meeting last week that the current carrying capacities now tabulated in the Rules rested for the first time on a logical basis; that is, a limiting rise of temperature had been adopted instead of a pressure drop. When it is remembered that the maximum increase in temperature permitted on this basis is only 20° F. in the case of rubber-covered conductors, it is obvious that there is a very large factor of safety; and the next step will now be to determine what is the maximum temperature rise that can really be allowed with safety. In view of the general desire that this should be done, we expect that when the seventh edition of the Rules makes its appearance the Table of Conductors will be still further modified. For the present, general satisfaction is expressed at the considerable saving that can be effected in the cost of wiring, particularly in heating and power installations, Mr. RAWLINGS going so far as to say that the recent revision of the maximum current-carrying capacities of conductors would do more than anything in the past to bring about a day load for central stations. Whilst welcoming anything that will cheapen the cost of installations, it must be remembered, however, that this is only part of the problem of encouraging consumers to adopt electrical apparatus, and most progress must be looked for from improved publicity methods, of which the new demonstration rooms of the Westminster Electric Supply Corporation, mentioned in our last issue, are typical.

Messrs. MELSOM & BOOTH'S Paper suggests several lines for further research; one, in particular, which should prove of exceptional value to the electric supply industry, is the comparative rise in temperature and the safe current-carrying capacity of underground cables laid on different systems. Preliminary investigations of this kind are referred to briefly in the Paper, and the results were reproduced in Fig 4 of our abstract last week, but these only apply to a single conductor; experiments on three-core cables would be particularly valuable, since the current density permissible in such cases would probably be much less than in the case of single cables. It is, however, useful to learn from the authors' experiments that the rise of temperature of a paper-insulated lead-covered cable laid in damp ground is less than half that where the cable is installed underground in an earthenware pipe.

Electricity Supply in the Colonies.

AFTER perusing the annual reports for the past year of electricity supply and tramway undertakings in this country, which are now coming to hand by almost every post, it is especially interesting to receive from Mr. O. V. THOMAS, engineer and manager of the municipal electricity supply department at George Town, Penang, a copy of his annual report for 1910. We notice that the metal-filament lamp has had an entirely beneficial effect on the business of the Penang undertaking, a very satisfactory result being the rapid extension of the supply to small consumers in the native business quarters, who require from three to six lamps each. During the past year the number of units sold to private consumers increased by over 40 per cent. but more striking, perhaps, is the fact that in recent year the output for public lighting has exceeded the privat supply. On the present occasion, however, the position i reversed, and the figures are 265,121 and 326,525 unit respectively. A traction supply of 200,090 units brings the total output to 791,736 units. For this output, the tota costs, excluding capital charges, were 9·94 cents (equivalent to about 2½d.) per unit sold, fuel accounting for 3 per cent. of the total. It is satisfactory to notice tha the balance of revenue over working expenses represente 9·6 per cent. on the capital expenditure, but owing to hig capital charges (interest 5 per cent., sinking and renewa

Digitized by Google

fund 3 per cent.) the net profit was only $9,698 (representing about £1,130); this, however, was considerably greater than in the previous year.

Publicity Committee Conference.—The Electric Supply Publicity Committee held its first annual conference at the Institution of Electrical Engineers on Tuesday, Mr. H. B. Renwick, Chairman of the Committee, presiding. There was a good gathering of leading representatives of the supply industry present, and a complete account of the proceedings will appear in our next issue. The Chairman reviewed the leading features of the work of the Committee, and referred to the large amount of literature which had been distributed relating to electricity supply for all purposes. He also expressed the satisfaction of the Committee at the result of the work accomplished.

Scientific Management.—The April number of the "Engineering Magazine" is a special issue devoted to the subject of Scientific Management, and among the contents we notice an article by Mr. R. W. Hutchinson, jun., on "The Applications of Electricity in Mining Industries." The author deals with the subject in a general way, illustrating the range of electrical applications to mining. He classes distributing systems for mines under three headings: (1) Continuous current for haulage, power and lighting; (2) continuous current for haulage and polyphase alternating current for power and lighting; and (3) high-potential alternating current for distribution to sub-stations, where it is converted into continuous current or low-pressure alternating current, or both. The first system is considered to be best adapted to mines in which power has not to be transmitted a great distance; the second for the same conditions in dusty or gaseous mines; and the third where a large mine or number of mines can be supplied from one central power plant. In future articles, cables and wiring, lighting, haulage, pumping, &c., are to be considered. Other articles in the special issue to which attention may be called are: "The Most Resourceful Utilisation of Water Powers," by Mr. H. von Schon; "Industrial Uses of Reinforced Concrete Construction," by Mr. J. P. H. Perry; and "Power Plant Betterment by Scientific Management," by Mr. W. N. Polakov.

The Discrimination of Colours.—In a Paper on this subject read at a meeting of the Royal Society, Dr. F. W. Edridge-Green stated that if a definite portion of the spectrum be isolated it appeared monochromatic, the size of the monochromatic region varying with the luminosity and wave-length of the light and the colour perception of the observer. Lord Rayleigh had expressed the opinion that he could discriminate between the colours in a monochromatic region even to the extent of distinguishing between the colours of the two D lines. The author, however, did not find this possible when special precautions were taken to have a pure spectrum and to avoid the physiological effect of contrast through varying intensities of the areas to be compared. The monochromatic area might be modified without altering its monochromatic appearance: the intensity of the light source being increased to compensate for the diminished luminosity. The monochromatic area might also be examined through a double-image prism, or be projected by means of a double-image prism upon a screen, so that the violet side of one area would be adjacent to and just touch the red side of the other area. In this way the monochromatic area might be made as large as desired, the intensity of the source of light being increased as required. An arc light gave two very bright areas of colour. This method was the most favourable for the detection of any difference; the monochromatic areas, however, still remained monochromatic.

Cable Interruptions and Repairs.

	Date of Interruption.	Date of Repair.
Assab–Perim	July 8, 1909 ...	—
Malta–Tripoli.....	April 20, 1910 ..	—
Latakia–Palurs	May 26, 1910 ...	—

Mr. W. E. Lane.—The Executive Committee of the Electro-Harmonic Society are organising a presentation to be made to the honorary secretary (Mr. W. E. Lane) on his marriage.

The Committee have thought that it would be the desire of members that the opportunity should be taken to present to Mr. Lane some slight token of their regard and of their appreciation of the services which he has ungrudgingly rendered with such conspicuous success as honorary secretary of the Society during the past 10 years. It is proposed that the subscription should be limited to 2s. 6d. each, in the hope that the full membership of the Society will participate. The Committee suggest that a list of the subscribers should be presented to Mr. Lane with the testimonial. Mr. R. K. Gray has consented to act as treasurer, and Mr. J. E. Kingsbury is acting as secretary to the fund. Contributions should be sent to Mr. Kingsbury, 7, Serjeants' Inn, E.C., before June 5.

Visual Sensation in the Alternating Magnetic Field.—In the April "Proceedings" of the American Institute of Electrical Engineers, Mr. A. H. Babcock refers to the recent Paper by Dr. J. B. Whitehead, of which an abstract was given in our issue of April 7th: Mr. Babcock points out that in 1897 while experimenting with some choke coils with large leakage connected across the receiving end of one of the first long distance high-tension lines placed in operation in Central California, a very marked sensation of flickering light was noticed whenever his head was moved through the leakage field. The matter was reported to the late Dr. F. A. C. Perrine and was investigated by him, though, if recollections of that occurrence are correct, he was practically the only one experimenting who did not corroborate the observations of the others. No record can now be found of any publication of these tests, though Mr. F. G. Baum confirms the writer's recollections of the experiments. The reactance used was a 150 kw. Stanley transformer of the vertical core type, in which the iron circuit was opened sufficiently to produce practically full-load current when the 2,200-volt coils of the transformer were connected across the station 'bus-bars and the high-tension coils were open-circuited.

Electric Lamps for Miners.—The Secretary of State for the Home Department announces that, in order to encourage the production of safe and efficient types of electric lamps for miners, a colliery proprietor has placed at his disposal the sum of £1,000 to be offered as a prize for the best lamp or lamps fulfilling the requirements specified below. Mr. Charles Rhodes (a former President of the Institute of Mining Engineers) and Mr. Charles H. Merz (a member of the Departmental Committee on the Use of Electricity in Mines) have consented to act as judges. The conditions of the competition are as follows:—

1. The competition will be open to persons of any nationality.

2. It will be in the discretion of the judges to award the whole of the prize for the lamp which they consider to be the best; or to divide the prize; or to make no award if no lamp appears to them to be of sufficient merit.

3. Lamps must be addressed care of C. Rhodes, Esq., at the Home Office Testing Station, Rotherham, and must reach the testing station not later than December 31st next; a spare globe should accompany each lamp.

The requirements which should be fulfilled by any lamps submitted for competition are as follows: (1) The lamp should be of sound mechanical construction so as to withstand rough usage. (2) The lamp should be of simple construction and easy to maintain in good order and repair. (3) The lamp should be so constructed as to render impossible the ignition of inflammable gas either within or without the lamp. (4) The lamp battery should be so constructed that any liquid which it may contain cannot be spilled when the lamp is in use, and means should be provided for dealing with any gas which may be generated by the battery. (5) The materials used and the construction should be such that metals and other parts will not be liable to deterioration by corrosion as a result of the action of the "electrolyte," &c., used in the battery. (6) The lamp should be effectively locked so that it cannot be opened without detection. (7) The lamp should be capable of giving an amount of light not less than 2 c.p. continuously for a period of not less than 10 hours. (8) The light should be well distributed outside the lamp. A movable reflector to concentrate or to shield the light may be provided.

In addition to the above requirements regard will be paid to (*a*) the first cost of the lamp; (*b*) the cost of maintenance; (*c*) convenience in handling; and (*d*) the weight of the lamp when charged and ready for use.

Hulton Colliery Disaster.—The reports of Mr. R. A. S. Redmayne (H.M. Chief Inspector of Mines) and Mr. S. Pope on the explosion at the Pretoria Pit last December have been issued by the Home Office this week. Mr. Pope's report deals

Digitized by Google

with the proceedings at the inquest and is concerned with the legal aspect of the question. He does not recommend any prosecution. Mr. Redmayne, after holding a formal investigation, states that he is perfectly satisfied that the use of electricity in the mine had no bearing on the disaster; and he has come to the conclusion that the explosion originated at a fall at the furthest in-bye point of the intake airway of the No. 2 face of the North Plodder. In all probability, he says, a second fall took place immediately before the explosion, accompanied by the liberation of a quantity of gas; and this gas was, in his opinion, ignited by a safety lamp becoming overheated, falling through the gas, or by its being damaged by the fall of stone. Mr. Redmayne suggests that mining engineers and others connected with the working of gassy collieries should seriously consider the possibility of the replacement, or partial displacement, of the gauze lamp in fiery mines by the electric lamp. The conclusion which he thinks may be drawn from the evidence submitted at the inquiry as regards the electrical plant is the importance of its proper supervision. A daily report as to the condition of the electrical apparatus was made at the mine, but it is not sufficient, he says, merely to state that the condition of apparatus was found to be "good." He is of opinion that the Hulton Colliery was understaffed. It is interesting to notice that the armoured cables in use throughout the mine satisfactorily resisted the effects of the explosive blast, heat and heavy falls of ground and were found afterwards to be mechanically and electrically perfect. It may also be noted that Mr. Redmayne considers it unwise to use electricity at the coal face in a gassy mine, such as this was, and that under the new Rules proposed its use would be prevented.

Tramway Progress in Berlin.—The report of the Grosse Berliner Strassenbahn for the year ended December 31, 1910, as published in the "Elektrotechnische Zeitschrift," shows that a dividend of 8½ per cent. was declared on a capital of £5,000,000. The rolling stock now consists of 675 double-truck motor cars, 917 single-truck motor cars and 1,036 trailers. The last mentioned have seats for 24 passengers and standing room for another 16 on the end platform. The number of passengers carried during 1910 was 427,700,000, as against 396,610,000 in 1909. The gross earnings were £2,038,560 in 1910 and £1,888,964 in 1909. The distances run were 60,281,160 car-miles in 1910 and 55,823,700 in 1909, the earnings being 8·4d. and 8·3d. per car-mile respectively. The operating expenses were 55·58 per cent. of the gross earnings in 1910, as against 54·82 per cent. in 1909; 7·04 passengers were carried per car-mile. The length of track is now 331·4 miles. £25,000 was placed to the road depreciation account and £26,250 to the account for renewal of rolling stock. Under the agreement with Berlin and the neighbouring municipalities the company paid over £139,320 of its gross earnings to the local authorities.

City and Guilds of London Institute.—The report of the Council for the year 1910 mentions that the Central Technical College will in future be conducted by a Delegacy representing the City and Guilds of London Institute, the Imperial College of Science and Technology and the Goldsmiths' Company, in pursuance of the supplemental charter recently granted to the Institute and the new schedule attached to the charter of the Imperial College. The name of the College will also be changed to the City and Guilds College (Engineering). In consequence of this change in the management a scheme has been provisionally adopted by the Delegacy involving the reorganisation of the mathematical and chemical departments. In recognition of their long and valuable services to the Institute, the Executive Committee has appointed Prof. Armstrong Emeritus Professor of Chemistry, and Prof. Henrici, Emeritus Professor of Mathematics and Mechanics, on their retirement at the end of the present session from their professorships at the City and Guilds College. The Council record their high appreciation of the services rendered by Profs. Armstrong, and Henrici since the establishment of the College in 1885, and of their untiring zeal in developing the courses of study in their departments. The annual report of the Dean, Prof. W. E. Dalby, which is contained in an appendix to the Council's report, refers, in addition to the usual statistics, to the increase in the equipment of the College. The total number of students attending diploma and special courses at the Central Technical College was 474 in the session 1909-10, compared with 469 in the previous session. Of these students 102 took the electrical engineering course, as against 113 in 1908-9 and a maximum number of 160 in 1904-5. The total number of students, however, receiving instruction in electrical engineering was 321 (including 80 students from the Royal College of Science and School of Mines), as against 318 in 1909. At the close of the session in July, 1910, the diploma of associate of the City and Guilds Institute was awarded to 80 matriculated third year students, as against 98 in the previous year. The diminution in the number of students entering the Technical College, Finsbury, is receiving the anxious consideration of the Executive Committee; the possible causes of the decrease are stated to be entirely external to the College; the one which has had most effect is believed to be the continued depression in the electrical industries; indeed, it is only in the electrical department of the College that any serious decrease in the number of students entering for the day course of instruction has occurred. The establishment of many other technical colleges both in the metropolis and the larger provincial towns has also had some effect, as well as the desire amongst students in recent years to obtain a university degree. If this desire should abate there should again be a demand for such courses as the Finsbury College was designed to provide. In the meantime some slight alterations have been made in the programme, the age of admission being raised from 14 to 15 years, and a regular time table arranged for third year engineering students. The total number of day students during the 1909-10 session was 153, as against 182 in 1908-9, the respective numbers taking the electrical engineering course being 57 and 67. The evening department of the College was attended by 233 students, compared with 291 in the preceding session.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. J. Rezelman contributes an article on "The Reactance of Asynchronous Motors with Squirrel-Cage Rotors."

Mr. H. Smith contributes an article on "A Method for the Detection of Harmonics in an Alternating Current, and for the Measurement of Inductances."

At the annual general meeting of the Institution of Electrical Engineers on Friday last the report of the Council was presented. We give an abstract of the report and also refer to it in our Leading Article.

We give an account of the discussion that took place at the Institution on Thursday last week when Messrs. Melsom and Booth read their Paper on "The Heating of Cables with Current."

At a recent meeting of the Institution of Mechanical Engineers Mr. J. E. Dowson read a Paper on "Gas Producers."

We describe a new form of telescopic mast.

At a recent meeting of the Derby Society of Engineers Mr. J. Hürdén read a Paper on "The Electric Furnace."

We give an abstract of an article in the "Electrical World" which describes a method of producing "artificial daylight" from the light given by a tungsten lamp.

The annual dinner of the National Telephone Co. last week, besides being the last official occasion on which the staff will so meet together, was noteworthy for an important statement by the Postmaster-General.

The report of H.M. Chief Inspector of Mines, Mr. R. A. S. Redmayne, on the Hulton Colliery explosion has been issued by the Home Office. Mr. Redmayne is of opinion that the electrical plant had nothing whatever to do with the explosion.

An interesting consular report from Norway gives particulars of the progress made in electric smelting of steel, &c., in Norway. A consular report also gives information as to the progress of hydro-electric schemes, construction of tramways, &c., in the United States.

Municipal Loans.—An inquiry was held at *Bradford* on Tuesday into the application of the Council for permission to borrow £50,000 for extensions of their electricity undertaking.—An inquiry was held at *Hull* on Wednesday into the application of the Corporation for

Digitized by Google

sanction to a loan for extensions of their electricity supply undertaking.

Legal.—Judgment was given by the Railway Commissioners on Monday in favour of the National Telephone Co. in regard to their application for a declaration that the terms of the agreement under which their plant, property, &c., are to be taken over by the Postmaster-General should be construed in a wider and more liberal spirit than that proposed to be adopted by the Postmaster-General.

Sheriff Gardner Millar on Monday dismissed the appeal of Glasgow Tramways Committee against the assessment of their undertaking.

On Friday last Mr. Justice Neville dismissed an application by the Z Electric Lamp Manufacturing Co. for an interim injunction to restrain the Osram Lamp Works (Ltd.) from threatening plaintiffs or their clients with legal proceedings in respect of alleged infringement of defendants' Letters Patent.

Companies' Reports.—The directors' report of Callender's Cable & Construction Co. gives an interesting *resume* of the progress made by the company during the past year.

OBITUARY.

E. Ristori.—We regret to record the death, which recently occurred, of Mr. E. Ristori, A.M.I.C.E. Mr. Ristori's early training in engineering was received in Italy. After some connection with railway work and explosives manufacture, he organised, in 1894, the British Aluminium Co., of which he was managing director until 1901, and he was responsible for the Kinlochleven power scheme of the company. Deceased was interested in electro-chemistry as well as electro-metallurgy.

Baron E. B. d'Erlanger.—The death is also reported of Baron d'Erlanger, who was chairman of the New General Traction Co. and a director of the Norwich and Coventry tramway companies.

PERSONAL NOTES.

Mr. F. Monkhouse, who for the past seven years has been assistant manager to Arc Lamps (Ltd.), has now terminated his connection with the firm, and communications may be addressed to Mr. Monkhouse, 17, Blandford-road, St. Albans.

The electrical engineer to the Corporation of London, Mr. A. A. Topham, has been granted further leave of absence owing to continued ill-health.

Mr. J. G. McLean has resigned his position as engineer and manager of the Woking Electric Supply Co., which he has held for over 10 years. Future communications for Mr. McLean should be addressed Heathside, Woking.

APPOINTMENTS VACANT AND FILLED.

Messrs. Mather & Platt (Ltd.), Park Works, Manchester, advertise for an estimating engineer, used to electric power schemes.

A junior clerk is required thoroughly experienced and competent for the office staff of works department of electrical undertaking in country town near London. Salary £156 per annum. See advertisement.

Wireless electrical fitters, experienced in fitting electrical installations, are required. Applications to the Electrical Engineer, H.M. Dockyard, Devonport. See an advertisement.

A lecturer in electrical engineering and allied subjects is required for the Natal Technical Institute. Salary £300, rising to £400. Further information from Mr. W. A. Narbeth, Langford House, Bexley, Kent, to whom applications by June 7.

A teacher of electric wiring is required one night a week during the present session at the County School, Twickenham. Salary for each lesson of 2½ hours. Applications by June 10 to Mr. F. [illegible], Council School, Stanley-road, Teddington.

A demonstrator in physics is required for Armstrong College, Newcastle-on-Tyne. Salary £100 rising to £120. Applications to Mr. E. H. Priest, Secretary, by June 23.

On Wednesday Lancaster Town Council appointed Mr. Geo. C. [illegible] who has been carrying out the duties on probation during the [illegible] months borough electrical engineer and tramways manager, and also decided to increase his salary by £50 per annum for [illegible] months.

Mr. R. K. Butler, shift engineer at Hounslow, has resigned to take an appointment with the Underground Electric Railways Co. and Mr. [illegible] Blake, an improver at the works, has been appointed to [illegible].

INSTITUTIONS AND SOCIETIES.

Association of Mining Electrical Engineers.—A largely attended meeting of the East of Scotland branch of this Association was held last Friday evening, May 26th, in the Royal Hotel, Dunfermline, Mr. C. Augustus Carlon, of the Fife Coal Co., in the chair. The following officials were appointed for the ensuing session: *President*, Mr. C. Augustus Carlon (Fife Coal Co., Leven); *Vice-President*, Mr. H. Gordon Fraser (Fife Coal Co.); *Hon. Secretary*, Mr. Thomas Davidson (16, Rutland-square, Edinburgh); *Hon. Treasurer*, Mr. Robert Scott (Musselburgh); *Council*, Messrs. David Beveridge (Kelty), W. E. Townsend (Edinburgh), James Walker (Lochgelly), J. M. Keenan (Niddrie), R. W. Hogarth (Edinburgh), Wm. Lang (Mary Pit, Lochore), Neil A. Wilkie and R. H. Willis (British Electric Plant Co.).

With a view to creating and stimulating interest in the branch the meeting discussed the desirability of holding a series of meetings in such districts as Wemyss (Fifeshire), Alloa (Clackmannanshire) and Polmaise (Stirlingshire). The general opinion was that if these meetings were methodically arranged and systematically organised they would result in a considerable accession to the membership of the branch.

Institution of Mechanical Engineers.—The annual conversazione took place on Friday evening last at the Institution, St. James's Park, S.W., the guests being received by the President (Mr. E. B. Ellington) and Mrs. Ellington. As on previous occasions there was no lack of entertainment, an excellent selection of vocal and instrumental music being performed. This was much appreciated; whilst for those visitors desirous of more technical entertainment a lecturette by Prof. E. G. Coker, D.Sc., on "Optical Determination of Stress" was provided. The success of the conversazione was attested by the large gathering who thronged the rooms and staircase of the Institution throughout the evening.

Royal Society of Arts.—The annual conversazione was held on Tuesday evening last in the Natural History Museum, South Kensington, the guests being received in the Central Hall by Sir John Cameron Lamb, C.B., C.M.G., chairman, and other members of the Council. The entertainment provided was more varied than usual. The band of H.M. Royal Artillery performed a selection of music in the Central Hall, whilst a vocal and instrumental concert was given throughout the evening in the Shell Gallery, and a miscellaneous entertainment in the Fish Gallery. The last mentioned programme included several dances and dialogues; but as nearly the whole of the audience had to view these through various cases of specimens, much of the entertainment was lost.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, June 2nd (to-day).

ROYAL INSTITUTION.

9 p.m. Meeting at Albemarle-street. Discourse on "Radio-telegraphy," by Commendatore G. Marconi.

THURSDAY, June 8th.

ROYAL INSTITUTION.

3 p.m. Meeting at Albemarle-street. Lecture on "Practical Progress in Wireless Telegraphy," by Mr. T. Thorne Baker.

FRIDAY, June 9th.

PHYSICAL SOCIETY.

8 p.m. Meeting at the Imperial College of Science. Agenda: "The Lüders Lines on Mild Steel," by Mr. W. Mason; "Exhibition of a Model illustrating the Passage of a Light Wave through Quartz," by Dr. H. S. Allen; "Tables of Circular and Hyperbolic Functions for Complex Values of the Argument," by Mr. A. Johnstone; "On the Measurement of Contact Differences of Potential," by Prof. A. Anderson and J. G. Bowen; "Exhibition of Gyroscopic Apparatus," by Sir G. Greenhill, F.R.S., and "A New Method of Approximate Harmonic Analysis by Selected Ordinates," by Prof. S. P. Thompson, F.R.S.

ROYAL INSTITUTION.

9 p.m. Meeting at Albemarle-street. Discourse on "Applications of Physical Chemistry to the Doctrine of Immunity," by Prof. Svante Arrhenius.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued for the current week:—

Monday, June 5th, "A" Company.—Technical Drill, 7 to 9 p.m.
Tuesday, June 6th, "B" Company.—Technical Drill, 7 to 9 p.m.
Wednesday, June 7th.—Gymnastic Classes, 7 to 10 p.m.
Thursday, June 8th.—Recruits' Drill (Infantry Drill), 7 to 8 p.m. Technical Drill, 7 to 8 p.m.
Friday, June 9th.—Recruits' Infantry Drill, 7 to 8 p.m. Technical Drill, 7 to 9 p.m.
Saturday, June 10th.—No parades.

THE PRESENT STATE AND FUTURE PROSPECTS OF HIGH TENSION CABLE MANUFACTURE.*

BY DR. LEON LICHTENSTEIN.

Cable manufacture is one of the oldest branches of electrical engineering, the first cables being made early in the eighties for direct current at 110 volts with insulation of impregnated jute; the first high-tension cables were made 10 years later with similar insulation, and were of the concentric type for 2,000 volts. Paper soon superseded jute, the first stranded cables for 10,000 volts with paper insulation dating from about 1900; and the first transmission scheme using paper cables at 20,000 volts was carried out in 1908, while nowadays such cables are ordinary up to 25,000 volts. Rubber cables have developed more slowly, and seem likely to recede in view of the price of rubber. The differences in rubber, due to source and the methods of the factory, make this kind of insulation likely to be unsuitable for power transmission in spite of its elasticity, flexibility and excellent water-resisting properties. The present article is therefore confined entirely to paper cables and their prospects.

The highest limits of voltage are far out of sight, for the present at any rate; but a few words are necessary to explain the present position, and relate to problems that have been already solved. High-tension conductors for 20,000 and 25,000 volts are made normally with conductors whose sectional areas range up to 400 sq. mm., and with external diameters over the lead covering up to 90 mm. or 100 mm. The thickness of the insulation varies from 11 mm. to 13 mm. Not many years ago 9 mm. of insulation were required for 10,000 volts; and this fact denotes progress, which is due not to a lower standard of safety in working but to improved chemical, physical and mechanical processes. The following figures taken from tests made in the Siemens-Schuckert works illustrate this. A number of short lengths of different types of three-core cable were taken. They were mostly about 5 metres long. One with 5 mm. of insulation between the conductors and between the conductors and the lead covering broke down at 70,000 volts in 30 minutes; another with 4·9 mm. of insulation broke down in 30 minutes at 50,000 volts; another with 6·4 mm. of insulation broke down in 5 minutes at 115,000 volts; a fourth, with 7 mm. of insulation, broke down in 5 minutes at 120,000 volts; and a fifth, with 12 mm. of insulation broke down in 33 minutes at 180,000 volts. These were admittedly newly made pieces that had not been bent to and fro in the manner usual for testing purposes; but the figures obtained from other pieces that had been so bent were not very largely different. In fact, this difference was so small that it might be well to advise the abandonment of bending tests, both in the interests of buyer and seller. Not long ago there was a difficulty in making cables with sector-shaped conductors with areas of more than 150 sq. mm.; but now they can be made up to 500 sq. mm., and are not much stiffer than with round conductors of equal capacity. They have, however, the advantage of being smaller in overall diameter and of weighing less.

The capacity of modern cable factories is of interest, but the following facts relate solely to that of the Siemens-Schuckert works, and though this may appear to treat the matter only from one point of view, it is probably better than to confine one's self to generalities which everybody already knows. The Nonnendamm works make cables, the cores of which weigh as much as 8,000 kg., in one length, the weight of the cable when ready for laying being about 15,000 kg. In order to give an idea of the size of a cable of this kind it may be said that an armoured three-core cable with conductors of 25 sq. mm. weighing 15,000 kg. is nearly 2 km. long. Still, it must be admitted that these great lengths are not very easily handled during the process of laying; but there is the great and counterbalancing advantage which results from an absence of joints, and which is very valuable with high pressures. The large armouring machines in the works are probably as big as any in existence. In one case the length of the machine is 30 metres, the number of wire coils is 48, each weighing when full 500 kg.; the whole is driven by a motor of 170 H.P., the speed of working being at the rate of 0·6 metre per second. Other machines for other processes are also of a similar size.

For power transmission, cables have the great advantage, as compared with overhead schemes, of freedom from the effects of lightning and other weather influences, and these points are not nowadays under-estimated. But the deciding factor is, often enough, the voltage; and this may have the effect of putting the cables out of court. Attempts to increase the practicable limit of voltage are not new. O'Gorman's proposal to build cables out of insulating materials of differing dielectric constants was theoretically interesting but insufficient from the practical standpoint. It is only quite lately that pressures of 50,000 and 60,000 volts have seemed possible. The railway from Dessau to Bitterfeld may be taken as a type of some of the latest work, energy being transmitted at 60,000 volts. The length of the transmitting cable, which duplicates an overhead line, is 4·5 km., and the frequency is 15. The cable system consists of two single cables buried in asphalt, the pressure between each conductor and the lead covering being therefore 30,000 volts; each cable was tested, after laying, at 50,000 volts to earth for 10 minutes. The results obtained in practice will be awaited with some interest. In further illustration of the probably practicable upper limit of voltage, from the point of view of the pressure-resisting capacity of a cable, it may be stated that at the Siemens-Schuckert works a cable length was taken which was 61 metres long and had 13 mm. of insulation. It withstood a pressure of 220,000 volts for 18 minutes and of 330,000 volts for several seconds without breaking down. Pressures of 50,000 and 60,000 volts are not, therefore, likely to be out of the question for transmission schemes for long.

But this change will not take place suddenly. The pressure is likely to be gradually raised from its present limit of 25,000 volts, but above 40,000 or 50,000 volts technical manufacturing processes are not the only things to be taken into consideration. Dielectric losses may be important enough to require careful estimation, and work has been done in regard to this matter by Humann, Monasch and Höchstaedter, the last of whom worked with pressures up to 60,000 volts, though confining his experiments to the cables of one factory. It is much to be desired that his experiments should be repeated by others so as to have a more general outlook on the possibilities of the future. Cables with two and three cores for 30,000 volts present no problems in dielectric losses of any importance, unless the length of the transmission line should be very great; but above this pressure, if progress is to be made, something will have to be done to convince possible buyers that their fears are groundless. The author's view is that cables carrying 40,000 volts can be safely recommended without fear of serious dielectric loss, even of the two and three-core types with single conductors the limit can be set much higher. Makers might, perhaps, undertake guarantees as to dielectric losses, and test the cable after laying in this respect, but for the present this suggestion must remain in an indefinite form. A necessary preliminary is to reconcile the ordinary methods of measurement by bridge and wattmeter. Höchstaedter's oscillographic methods are too cumbersome for everyday use. It may be here mentioned that Siemens & Halske are making wattmeters which read accurately with power factors of 0·03 and even less. These instruments have an astatic arrangement which frees them from being susceptible to the action of an external field.

The effect of the dielectric losses on the temperature of the cable requires a few words of explanation. The following experiment shows the nature of this effect and its extent. A three-core lead covered cable without armouring, 15 metres long, was put under a pressure of 80,000 volts for 5 hours. The sectional area of the conductors was 50 sq. mm., and the thickness of the insulation 13 mm. A thermometer was attached to the lead covering, and the readings were taken through a telescope. When a condition of equilibrium had been reached, it was found that the temperature was about 3° above that of the atmosphere. At 40,000 volts the rise would be less than 1°C., and if the cable were buried in the ground it would be even less than that. From this it seems that the dielectric losses up to 40,000 or 50,000 volts are unimportant in cables of good make. The determination of the losses under these conditions by the buyer or in his interests, could only have the effect of excluding cables which were reasonably defective even though they could withstand the pressure tests.

The heating of high-tension cables requires some new elements to be taken into account. It is fair to say, for instance, that since the regulations of the Verband Deutscher Elektrotechniker were drawn up the situation has been somewhat modified. A high-tension cable must be classified not so much by voltage as by thickness of insulation. Latterly the sizes have considerably increased. The tables, which have been published under authority, allow only for single cables with 2 mm. or 3 mm. of insulation, and for two and three-core cables up to 9 mm. This ought now to be extended up to 15 mm. or 16 mm. of thickness of insulation; greater thicknesses than these are somewhat rare. As a result of experimental work, the author published some years ago the currents which could be carried by single cables up to 5 mm. of insulation by single cables, and by three-core cables up to 17 mm. If these figures are further corrected for the heating due to dielectric losses, they show that the loads allowed by the official regulations ought to be decreased by about 30 per cent. The figures only extend up to 120 sq. mm. of sectional area, and therefore need amplification. Cables for more ordinary voltages also need further consideration in this respect, especially seeing that everybody who has anything to do with estimates for cables and transmission schemes knows that the governing factor is the permissible tempe-

Digitized by Google

ture rise and not the voltage drop along the line. Questions as to capacity also arise, though they are only important beyond 30,000 volts and on very long lengths of cable. At any rate, below 20,000 volts, capacity need not be taken into consideration, and it is necessary to emphasise this point, seeing that buyers often make careful demands with regard to this point, which they complicate by all sorts of hypothetical conditions which they consider possible but are in reality quite unlikely. Obviously, the capacity has nothing to do with the pressure-resisting qualities of the cable, and it is not easy to understand the importance which a buyer thinks ought to be attached to the capacity of a cable which is to be used on direct current at 220 volts. The capacity of a cable decreases with increasing thickness of insulation, but the charging current is proportional to the voltage and the length of the line, which are often interdependent quantities. The charging current often rises very much with the voltage. Taking a concrete case: suppose 10,000 kw. is to be transmitted with a frequency of 50 and a power factor of 0·9 and a loss of 5 per cent. At 20,000 volts a three-core cable of 185 sq. mm. sectional area of conductors would be required having regard to the permissible heating, and the length of the line would be 15·5 km. At 50,000 volts the cable would have a sectional area of 70 sq. mm. and the length of the line would be 35·6 km. The capacities of the two systems per kilometre would be 0·28 mfd. and 0·18 mfd. and the charging currents per kilometre 1·76 and 2·83 amperes, the total charging currents being 27 and 100 amperes. That is to say, at 50,000 volts the charging current is 8·4 per cent. and at 50,000 volts 17 per cent. of the working full load current. This gives some idea of the problems which lie before the designer of the future. A large charging current is obviously a nuisance. At no-load it indicates a certain loss, and leads to difficulties owing to well-known properties of alternating machinery, which would be particularly noticeable on rapidly fluctuating loads. At full-load things are certainly different, and the charging current tends to improve the load factor. One remedy for all this is, obviously, to lower the frequency. This at once decreases the dielectric losses and the charging current. Frequencies of 25, and even of 15, have been found suitable for railway work, but for ordinary transmission work a frequency of 25 in connection with cables has not been sufficiently tested. It cannot, therefore, be said that a lowering of the frequency is always practicable.

Another method is that of compensation by choking coils inserted in parallel, and this has been specially examined by Roessler in his work on the subject. Undoubtedly a suitable design of choking coils in the generating station would much improve the power factor of the generator; but it would do nothing to touch the heating referred to the charging current. Several choking coils at suitable points on the line would be necessary, but a great deal would still be open to discussion, including questions affecting the size, position and construction of the coils. It might well be the subject of useful experimental work for somebody to carry out Roessler's suggestions at 50,000 volts on a cable transmission line. Transformers on consumers' premises may somewhat tend to neutralise the charging current, and something might, perhaps, be done by suitably designing these transformers, though it is not easy to say exactly how much. The problem touches largely unexplored ground, but it is by no means only of theoretical interest. It has very serious practical importance, and with the electrification of main railway lines some means will have to be discovered for neutralising heavy charging currents at 40,000 and 50,000 volts. Neither is the matter likely to be without influence on the design of generating machinery, which must be capable of giving a fluctuating output under these exacting conditions at a constant voltage.

A few words may be devoted to the unavoidable joints and end-connections on high-tension cables. On ordinary voltages they sometimes give trouble, and this is hardly to be wondered at seeing that a cable is a purely mechanical product while a joint contains much of the human element and is often made under most awkward conditions in the open street. Big cable companies have much greater chances of success in this work than small private buyers. They have more experienced workmen, and possibly a greater interest in success, even though careful supervision on the spot is generally impossible. At high voltages this is still more important, and it is hardly too much to ask that the laying of these cables should be entrusted always to the makers. At the present moment, the makers are able to undertake satisfactory joints and end-connections for 60,000 volts, and the work done on the Dessau-Bitterfeld line may be quoted as a case in point, where the end connections were tested at a pressure which corresponded to 240,000 volts between the conductors.

As for the testing pressures that will have to be employed in the future, these will doubtless be very high. Probably, however, at very high pressures an excess of 25 or 50 per cent. over the working pressure ought to suffice. Still assuming that double the working pressure is still considered necessary, a pressure of 120,000 volts will be required. The Siemens-Schuckert works are extending their testing arrangements in view of general expansion, and a description of their new arrangements will probably be made public before long. Supposing an output of 400 kv.-amperes to be available, this would suffice for a length of 0·5 km. of cable of 95 sq. mm. sectional area at 120,000 volts, and for four times this length at half the pressure. This is, of course, a pretty considerable output for a purpose of this kind, though the real output, represented by the driving motor, is obviously much less than the apparent output. As for the testing of cables after laying in position, it is probable that pressures of 80,000 and 100,000 volts will have to be considered.

THE ELECTRIC FURNACE, WITH SPECIAL REFERENCE TO THE MANUFACTURE OF HIGH-CLASS STEEL.*

BY J. HÄRDÉN.

Summary.—After referring to early arc and induction furnaces, the author describes the Roechling-Rodenhauser furnace, and gives particulars as to the costs of operation. He next describes the "Paragon" furnace, a combination of an arc and a resistance furnace, and discusses generally the field for electric furnaces.

The author first describes briefly early experiments with electric furnaces, referring to the work of Siemens, Ferranti, Moissan, Stassano, Héroult, Girod and Kjellin, and explaining the features of arc and induction furnaces.

The induction furnace is admirably adapted for melting pure raw material in charges up to 2 or 3 tons; but, owing to its nature, it is not a refining furnace, or suitable for the purification of inferior grades of steel in large quantities. The essential of rapid and efficient refining demands that a large area of the charge shall come in contact with the slag used for refining. If the Kjellin furnace was specially constructed for refining, the power factor would be unduly low and the handling of the slags most difficult. To overcome this defect the firm of Hermann Roechling & Co., of Volklingen, Germany, who had experimented with an 8-ton Kjellin furnace at their works, designed the modified induction furnace known as the Roechling-Rodenhauser furnace. In this two or three limbs of the core pass vertically through the hearth, the energising coils being placed on these limbs in a similar manner to those in the Kjellin furnace. In addition to this, a special secondary winding of heavy copper bars is also placed outside and around the primary coils. The combined power induced in these secondary windings is about 35 per cent. of the total power of the furnace; the remainder is directly transmitted by induction to the charge.

The current induced in the secondary copper winding is conveyed to a set of steel plates inserted in the walls of the lining; these plates are covered with a material forming a conductor of the second class. Consequently, when the molten charge of pig-iron is poured into the furnace, these portions of the lining will become conductive, and allow the current to pass through. They then act as a kind of Nernst glower on a large scale, which, after being heated by the current, in turn heats the steel. The effect of this arrangement is that a much larger hearth can be used, because the close proximity of the secondary coil to the primary tends to increase the power factor considerably, also a high degree of refining can be carried out in a most economical manner.

It is ordinary practice to take hot basic Bessemer steel having an an analysis of about C 0·3 per cent., S 0·07 to 0·08 per cent., P 0·06 to 0·07 per cent., and refine to high grade steels of the analysis required with only traces of S and P. The consumption of electric energy will vary from 100 to 300 kw.-hours per ton, depending upon the degree of refining required. A specimen charge is as follows:—

Basic Bessemer steel charged: S 0·071, P 0·077.

Finished steel: C 0·14, Si 0·01, Mn 0·41, S 0·032, P a trace.

This steel is specially suitable for tubes for marine water-tube boilers.

In order to give an idea of the cost of the operation, the materials used and the kilowatt-hours consumed are given below, from which calculations can be readily made:—

			s.	d.
Weight of finished ingot			7,000 kg.	
Materials and alloys used:—				
Lime	550 kg. at	10s. per ton	5	6
Roll mill scale	30 kg. at	13s. ,,	0	4
Ferro silicon (50 per cent.)	30 kg. at	200s. ,,	6	0
Ferro manganese (80 per cent.)	20 kg. at	180s. ,,	3	6
Cost of materials per 7,000 kg.			15	4

Power consumed per 1,000 kg. (1,381 kw.-hours divided by 7)=197 units at 0·25d. per unit	4	2
Lining	0	10
Labour	2	0
Per 1,000 kg.	9	2½

Another combination of this type of electric furnace and the open-hearth furnace has been in operation for some time. In this case, hot basic pig-iron analysing approximately C 4·0 per cent., P 1·8 per cent., S 0·6 per cent., is charged into a 25-ton Wellman gas-heated rolling furnace. This furnace is used to reduce preliminarily the carbon and phosphorus by the addition of ore, &c., and at the same time takes the place of a mixer. Charges of about 3½ tons at a time are withdrawn and charged into an electric furnace, where the phosphorus is eliminated, and finished in a second electric furnace of the same size, where the sulphur is extracted and carbon and other corrections made. The P and S are easily reduced to traces.

There are several electric furnaces at this plant, the steel made being used chiefly for steel castings. The whole of the electric power is generated by blast-furnace gas engines at a very low cost per kilowatt-hour, and consequently the costs of refining are exceedingly low.

A special feature of the furnaces built on the induction type, either of the Kjellin or Roechling-Rodenhauser system, is their very steady load. In this respect these furnaces compare very favourably with the true arc furnaces, where the whole of the power is transferred to the charge through one or more arcs. Owing to the unavoidable irregularities on the surface of the charge in arc furnaces, the resistance of the arcs varies constantly, and causes the current to fluctuate violently. Consequently, it is necessary to provide for a generator of considerably larger kilovolt-ampere capacity and fly-wheel effects than would be required if the furnace imposed a steadier load.

It is true, however, that the induction furnace has a lower power factor. As a comparison, take a furnace of each type of a capacity of 5 tons, to be operated in each case from a 25-cycle generator. A furnace of the Roechling-Rodenhauser type will have a power factor of 0·65 to 0·70, while a plain arc furnace has a power factor of about 0·85 to 0·9. This is, in the latter case, due to the fact that the arc furnace is operated at a low voltage, 60 to 70 volts only in the arcs, and a correspondingly high current, which will cause a lower power factor than usual, owing to the inductance set up in cables, &c. (*see* "Electro-chemical and Met. Ind." for 1909). The power fluctuations in an arc furnace may vary between 0 to about 35 per cent. overload (*see* "Transactions" of the Iron and Steel Institute for 1909). Let us assume, say, 25 per cent. The total power supply may in both cases be about 520 kw. This means a generator capacity of 750 kv.-amperes for the induction furnace, and for the plain arc furnace $520/0{\cdot}9+145=725$ kv.-amperes. The difference is, as will be seen, very slight, and may even be in favour of the induction type if it is considered that the generator for the plain arc furnace must be built mechanically strong enough to withstand the current fluctuations.

It has been stated that steel produced in arc furnaces shows a lack of homogeneity and the presence of "ghost lines." It is probable that for these reasons Stassano designed the device of rotating his furnace on a vertically inclined axis. In induction furnaces, especially those of the three-phase type, the charge acts somewhat as the rotor in an alternating-current motor, and produces a very strong and efficient mixing of the charge. In fact, this rotating effect is sometimes so strong that certain measures must be taken to counteract it.

It has long been recognised by steel makers generally that, although the plain induction furnace is an excellent tool in the hands of the crucible steel maker, a furnace which would permit more extensive refining, and also the construction of large units, at the same time having the advantages embodied in the induction furnace system, is much to be desired. It is because of the comparatively low power factor of larger furnaces of the plain induction type that this class of furnace has not been constructed in large units to any great extent. In order to overcome this, the Roechling-Rodenhauser furnace, which is partly a resistance furnace and partly an induction furnace, was designed. A considerable number of these furnaces have been erected and are in operation abroad, giving very good results. Some steel makers, however, are of the opinion that it would be an advantage if a furnace could allow superheating the slag for refining purposes, but at the same time enable the metallurgist so to regulate the heat of the charge that gases could be expelled without difficulty. At the same time, the perfect circulation of the bath should be maintained so as to secure a perfectly uniform material.

A new furnace on these lines, which has been given the name "Paragon" furnace, has been designed by the Grondal Kjellin Co. This furnace is a combination of an arc and a resistance furnace, which makes it very much like an open-hearth furnace, and it may, indeed, be worked exactly in the same manner. The slag blanket is kept at the desired temperature by means of arcs playing over the surface of the slag, while the remainder of the heating power is transmitted to the bath by means of terminal plates, such as are used in the Roechling-Rodenhauser furnace. The result of this combination is that the slag may be heated to any desired temperature while dephosphorisation and desulphurisation take place; but the heating effect of the arcs need not be increased to such an extent as to keep the whole charge superheated, which, of course, would tend to overheat the steel immediately beneath the arcs; but a carefully regulated amount of current can be at the same time sent through the resistance plates, thus also heating the charge from underneath.

When the dephosphorisation and desulphurisation is finished it may be desirable to alter the gradient of heat in the furnace so that the lower portion of the bath is hotter than its surface, in order to expel the gases more readily. This result is obtained by diminishing the power transmitted through the arcs and increasing the power transmitted to the side plates. In fact, it is even possible to extinguish the arcs for a time and keep the bath liquid by means of the side plates, which for this purpose are provided with a cooling device of enforced air. The metallurgist has, therefore, the power of controlling the gradient of heat in the bath at will.

This combination has another advantage—viz., that the electrodes do not require to be of such large section for a given capacity of furnace as would be the case if the total amount of power were transmitted by means of the arcs only, owing to the fact that normally about 50 per cent. of the total power is transmitted through the arcs, while the other 50 per cent. is transmitted through the side plates. The advantages claimed, therefore, are threefold. Firstly, the size of electrodes for a given furnace capacity is only about half that of an arc furnace, and, consequently, with a given electrode section available, the melting capacity of the furnace can be nearly doubled. Secondly, the roof is not subjected to such severe strain, owing to the reduced size of the electrodes and to the smaller amount of power transmitted through the arcs; therefore the maintenance of the furnace costs less and the roof lasts longer. Thirdly, the control of the load factor of the furnace is better, because the current flowing through the resistance plates is perfectly steady, whereby the heavy current fluctuations otherwise caused by large arcs are very extensively compensated. The result is that no special machinery is required either for compensating for the lower power factor of a true induction furnace, or designed with a large flywheel effect, as in the case of a simple arc furnace, on account of its fluctuating load factor.

The power consumption per ton of steel should also prove more economical by means of this combination, as the high temperature of the steel is only required during desulphurisation, it being well known that dephosphorisation does not require such a hot slag as desulphurisation, and it follows that the higher the temperature of the steel for any length of time the greater also the heat losses during the process. In view of this, the total melting and refining process should be more economical with this combination. It therefore appears that this type of furnace includes several of the advantages of the induction furnace—viz., a good circulation of the charge inasmuch as it is heated from below as well as from above, and a high load factor. The power supply transformers also may be situated in an adjoining building, protected from dust and injury and entirely beyond the reach of the workmen. The low voltage current only requires to be transmitted to the furnace by means of insulated 'bus bars and cables.

In conclusion, a few words should be said to correct a widely spread misconception with regard to the scope of electric furnaces generally. It is frequently assumed that the electric steel furnace is intended to supersede and render obsolete the open-hearth furnace. This assumption is quite incorrect. It appears to be far more economical, however, at least in cases where large quantities of medium quality steel are required, first to melt the material in a gas-fired furnace, remove the carbon and phosphorus, which require only a comparatively low temperature; then to pour the partially refined steel into the electric furnace, where the phosphorus, sulphur, occluded gases and other injurious compounds can be removed. The removal of these latter impurities requires a considerably higher temperature than the foregoing stages, and it is obvious that if the temperature must be raised by means of a gas flame applied on the surface of the bath the heat losses must be very great.

The elimination of the occluded gases is the last and, it may be said, perhaps the most important stage of refining, if a really high quality of steel is to be obtained. In order to meet this demand the Grondal Kjellin Co. have also designed a furnace called the gas-fi

Digitized by Google

Paragon furnace. The furnace is essentially designed like an ordinary Siemens open-hearth furnace with basic lining, while terminal plates are built in in the sides, as in the case of the Paragon furnace previously described. The charge is melted and pre-refined by means of gas in the ordinary way, after which it is de-gasified by means of electric heating only.

In the case of an open-hearth furnace gas is constantly supplied, together with oxygen sufficient for the combustion. If the flame is made to be reducing—*i.e.*, not to have any excess of oxygen—it is difficult to obtain the desired temperature; but it is just this very oxygen that is to be expelled. Hence it is obvious that the electric heating will be of the greatest use in this latter stage. And this is just what the Continental steel makers have recognised, and have, therefore, installed their electric furnaces in conjunction with open-hearth furnaces; in fact, instead of discarding any existing open-hearth in favour of the electric furnace, new ones are being built. In fact, no less than 30 induction furnaces are in existence or under construction.

In the case of crucible steel the problem is different. Here, where no impurity whatever is tolerated, and where the price of the steel is high, the exclusive melting by means of the electric furnace seems fully justified and economical, as experience has clearly shown. The same also applies to places where natural sources of power, other than coal are available, where it probably will be found cheaper to produce the steel wholly by electricity instead of transporting coal.

GAS PRODUCERS.*

BY J. EMERSON DOWSON.

Summary.—A brief survey is here made of certain types of gas producers, the theory of their action and the composition of the gas produced being given. A comparison is also made between suction plants and pressure plant, and the effects of varying loads, &c., are discussed.

The author here considers only certain types of gas producers, and discusses their leading features from the theoretical and practical points of view. He proposes first, however, to review briefly the principles and conditions on which the production of producer gas depends, and it will be seen that, subject to minor variations, the chemical reactions are and must be the same in kind for pressure or for suction gas. In practice the gas used for furnace work is generally made from bituminous coal, and for engines and small heating work it is made from bituminous or semi-bituminous coal, or from anthracite or coke; but in some cases brown coal, lignite, peat, charcoal, &c. are used. The composition of the gas is largely influenced by the nature of the fuel, but a further important consideration is that for nearly all purposes (except furnace work) the gas must be free from tar and other condensable products. Speaking generally, producer gas is made by forcing or drawing air (with or without the addition of steam or water vapour) through a deep bed of fuel in a closed producer, an important characteristic of the process being that no external heat is applied.

If there were a shallow fire in the producer and an abundant supply of air, the carbon and other combustible constituents of the fuel would be completely oxidised, and the products of this complete combustion would be incombustible and useless as a gaseous fuel. If, however, there is a considerable depth of fuel in the producer (as there should always be in practice) there will be an excess of highly heated carbon, and this will react on the carbon dioxide and reduce it to carbon monoxide. The proportion of combustible to incombustible gas necessarily depends on the fuel used and on the actual conditions of working.

The final result of the complete combustion of carbon is the same whether it takes place all at once in an open fire, or whether carbon monoxide is first formed in the producer and is afterwards burnt to carbon dioxide. Theoretically when carbon is converted to carbon monoxide in the producer about 30 per cent. of the heat of combustion of the carbon is liberated; the remaining 70 per cent. will be liberated when the carbon monoxide is afterwards burnt to carbon dioxide in a furnace, engine, &c. It should, however, be understood that all the heat set free in the producer need not be lost, a large proportion being carried away in the form of sensible heat by the gas. In furnace work when the furnace is close to the producer, the loss of sensible heat is small; but when the gas is used for engines or for heating work requiring small cocks and burners, it must be washed and scrubbed, involving cooling and a considerable loss of sensible heat. When the air used for making gas in the producer is mixed with steam, the heat losses are reduced, part of the sensible heat being absorbed.

* Abstract of a Paper read before the Institution of Mechanical Engineers.

The following figures show the composition of the gas made in the Siemens producer from bituminous coal and in the author's own producer of the steam-jet pressure type (with superheated steam) with anthracite:—

	Percentage by volume.		
	Siemens.	Dowson.	Mond.
Carbon monoxide	23·7	25·17	11
Hydrogen	8·0	18·9	29
Carbon dioxide	4·1	5·98	16
Nitrogen, &c.	64·1	49·36	44

As anthracite yields less hydrogen than bituminous coal, the increase of hydrogen (derived from the steam) is therefore very marked. The weight of steam decomposed varied from 0·5 lb. to 0·7 lb. per pound of fuel gasified.

The above table also gives the composition of gas from a Mond producer, where an excess of steam (over 2 lb. per pound of fuel) is used to favour the production of ammonium sulphate.

When the author first used producer gas to work gas engines the compression pressures were low compared with those now in use, and it was considered important to have as high a percentage of hydrogen as possible, as it insured the prompt ignition of the charge in the cylinder. Much higher compressions are now used, chiefly because they raise the heat efficiency of the engine; and as the mixture of gas and air is more highly compressed it is ignited more readily. It has, therefore, become less important to have a high percentage of hydrogen; in fact, it is now considered by many to be a drawback, as there is then greater risk of pre-ignition. From the engine point of view it is better to limit the quantity of steam, but for the practical working of the producer it is still desirable to use a liberal quantity to check the formation of clinker and to reduce the loss of sensible heat. It is difficult to meet these somewhat conflicting ideals, and in practice a sort of compromise is effected by having about 12 to 15 per cent. of hydrogen in the gas. For large furnace work it is often best to have the gas as dry as possible when it reaches the furnace, as the presence of steam lowers the flame temperature. For such work the temperature of saturation of the air-blast for the producer usually varies from about 40°C. to 60°C., but this depends a good deal on the size and character of the coal used in the producer.

Lowe, of the United States, made in 1874 a new departure altogether, and produced what is technically known as "Water Gas." It usually contains approximately 44 per cent. by volume of CO, 48 per cent. of H, 4 per cent. of CO_2, and 4 per cent. of N_2.

Suction plant is next discussed. The production of the steam required to make good gas and to keep the temperature of the fire low enough to prevent the formation of an excessive amount of clinker presents many difficulties. Some makers have a water vaporiser inside the producer, whilst others prefer to have the vaporiser outside the producer and to heat it by the sensible heat of the gas after it has left the producer. The latter system has the advantage of cooling the gas more, but the amount of steam raised is less than in the other systems, and there is the risk that the gas will not always be hot enough to make the full quantity of steam required. This not only affects the percentage of hydrogen, &c., in the gas, but has an important bearing on the formation of clinker.

Apart from producing a sufficient quantity of steam when the maximum volume of gas is required, there is the further necessity for regulating the quantity of steam drawn into the fire when the load on the engine is variable. Some makers of suction plants try to get over the difficulty by having regulating valves worked by the engine, by means of which the admission of steam to the fire is governed by the engine. Some merely allow a vent in the vaporiser for the excess of steam to escape when the load is reduced; others have used the suction of the engine to draw water into the vaporiser in very small quantities, just enough at each suction stroke to give the steam re-

Table I.

quired for the quantity of gas to be consumed. This can only be done provided the vaporiser flashes the water into steam.

To compare the gas made in a suction plant with that made in a steam jet pressure plant of the same power, the author gives in Table I. the percentage composition by volume of the gas with a 40 B.H.P. plant of each type working with anthracite, and also the average results of seven different pressure plants of various sizes ranging from 8 H.P. to 300 H.P.

From this it appears that the calorific power of the pressure gas is approximately 20 per cent. higher than that of the suction gas. There is also rather more fluid friction to allow for when suction gas is used. The practical result is that there is a loss of about 5 per cent. in the maximum power of the engine when worked with suction gas. This is not important for small engines, but for those of larger size it must be considered. On the other hand, the heat efficiency of a pressure plant with independent boiler must necessarily be lower than that of a suction plant.

In considering the two types of plant for engine work, our general conclusions may be as follows: A suction plant has certain practical advantages: it costs less and occupies a smaller ground space, but the gas made in it is not so strong as in the older form of pressure plant, and in some cases this advantage of the latter is important. The fuel consumption per horse-power-hour and the labour required are about the same in both types of plant, provided the steam required is raised without an independent boiler. The consumption of water is the same in both types. It is also worth mentioning that where there are several engines to serve, the arrangement of the gas pipes is greatly simplified, and their cost is proportionally reduced, also the engines can be started more readily, when the gas can be taken from a small gasholder instead of from several suction plants.

As to variations in the quality of suction gas when the engine is working with light and variable loads, in a suction plant the quantity of gas produced is regulated by the action of the engine, as there is a draught of air and steam through the producer every time gas is admitted to the engine. Speaking generally it may be assumed that the best gas will be made when the producer is worked uniformly near its maximum capacity. At any rate of production considerably less than the maximum the calorific power of the gas will be lower. To test this practically, the author had some trials made with a 40 B.H.P. engine working with a full load and with no load at all. The gas was made with ordinary gas coke. The following analyses represent the average percentage composition by volume of the gas in each test:

Table II.

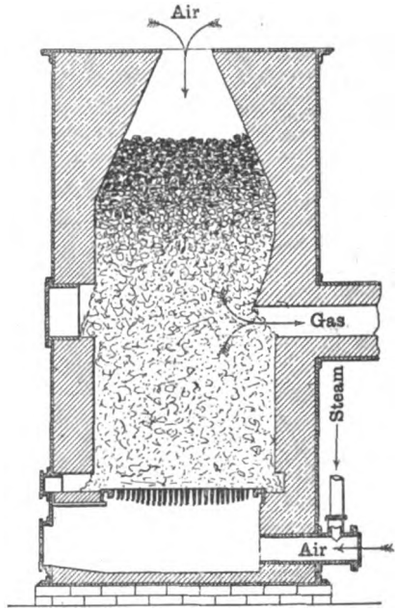
—	Full load.	No load.
Carbon monoxide	27·65	22·4
Hydrogen	9·85	7·0
Carbon dioxide	3·8	4·9
Oxygen	0·3	0·5
Nitrogen, &c.	58·4	65·2
Calorific power.		
B.Th.U. per cubic foot	128·9	101·0
Calories per cubic metre	1,147	899

The author had this further tested at Derby (1906) during the trials of suction plants made on behalf of the Royal Agricultural Society. As was to be expected, the gas contained smaller percentages of carbon monoxide and hydrogen, and larger percentages of carbon dioxide and nitrogen during the no-load periods. Also it was noticed that while the gas made with no-load on the engine, immediately after starting in a cold producer, had a low calorific power and did not materially improve while the producer continued to work without load, yet after the producer had worked for a time at full load, and had become thoroughly heated up, with a good depth of bright fire, it gave gas of considerably higher calorific power than before when the load was again removed. The explanation of this is mainly a question of temperature.

If the producer were worked by the continuous suction of a fan, instead of by the frequent intermittent suctions of an engine, the quality of the gas would be practically the same under full load, but during the no-load period the effect would not be quite the same. With a fan there would be a steady draught of the volume of air required, and there would be a shallow zone of fire near the grate, which would be maintained at a sufficiently high temperature to make good gas; and gas of good quality would be produced as long as this hot zone was sufficiently deep in relation to the size of the fuel. If the air for the producer were drawn in by an engine without load a greater depth of fuel would be heated by reason of the more rapid draught of air through the fire; but a good deal of heat would be dissipated before the next suction. This points to the importance of maintaining the temperature of the fire as high as possible when the producer is worked at a reduced load by the suction of an engine; and a step in this direction is to reduce the quantity of steam proportionally to the volume of air drawn in. It is not easy to fulfil all the conditions without complicating the apparatus, but it is well to consider what will give the best results, so that a near approximation may be obtained.

It is well known that after an engine has been working under a light load for some time with a suction plant there is risk of stoppage if the full load is put on suddenly. Moreover, when this occurs, it is often attributed to an insufficient supply of gas. This is a mistake, as the volume of gas necessarily varies directly in proportion to the load on the engine; it is the quality of the gas which is at fault. During the light-load period the temperature of the fire falls, and for a few moments after the full load has been put on the fire is not hot enough to effect the necessary chemical reactions. There is too little hydrogen, and not enough of the carbon dioxide is reduced to the monoxide. The remedy is to put on the full load more gradually, so that the engine may be kept running at full speed in spite of the weakness of the gas, and to check the admission of air to the cylinder; the fire in the producer will recover rapidly, and there will soon be a full supply of gas of good quality. The author gives particulars of some tests to illustrate this point.

Analyses of suction gas made in small plants have been given, and the author next gives the composition of the gas made in a 350 B.H.P. suction plant of his design. The fuel used was "carbonite" from Huddersfield, and during an ordinary day's run the average percentage composition by volume of the gas was:—Hydrogen 7·92, carbon monoxide 30·38, carbon dioxide 3·04, oxygen 0·42, nitrogen



DOWSON PRODUCER.

58·37. The percentage of hydrogen was low, but the CO was high, and with its high compression the engine worked well.

It has been shown that producer gas can be obtained with almost any kind of carbonaceous fuel, but for engines and small heating work all tarry vapours must be eliminated before the gas reaches the valves, cocks, &c. Hitherto this has been done by centrifugal tar extractors, washers, and other apparatus which add to the complication and cost of the plant. Some attempts have been made to draw off the tarry vapours from the upper part of the producer and to return them to the lower part of the fire where combustion takes place, but so far as the author is aware none of these plants have been altogether successful, as some of the tarry vapours go forward with the gas and must be removed by extractors or washers, &c. Another method of fixing the tarry vapours is to work the producer with a down draught instead of an up-draught. In this way the tarry vapours from the raw fuel (put in at the top) are compelled to pass through the whole depth of the fire so that they may be converted into fixed gases. It is almost impossible to do this effectually in continuous work, owing to the difficulty of maintaining a suitable temperature. It is also difficult to burn the fuel completely, and usually there is an accumulation of small carbon or coke, mixed with clinker and ash, in the lower part of the producer.

The author has always held to the opinion that the tarry vapours should be got rid of in the producer itself, and that it cannot be right to let tarry gas leave the producer, and then be obliged to remove the tar by extractors, &c. With this in view, he designed, in 1903, the

Digitized by Google

producer illustrated herewith. This producer is double acting—that is, air is drawn in through the top and through the bottom of the fuel column. The coal is put in at the top, and the upper part of the fire burns downwards. The hydrocarbons are distilled off and various useful reactions occur; the coke which remains sinks down gradually into the lower part of the producer. The coke is there converted into ordinary producer gas by the upward current of air (accompanied by steam) which is drawn in at the bottom. The mixture of gases leaves the producer through an outlet about half-way between the top and bottom.

When working with ordinary bituminous coal, or with lignite and several other varieties occur, there is no tar; it is disposed of altogether in the producer, and no mechanical or other tar extractor is required. After leaving the producer the hot gas passes through an external vaporiser, to cool the gas, and so raises the steam required for making the gas. It then passes through suitable scrubbers and is ready for use in the engine to be worked with it. This bituminous plant can be worked by the suction of an engine, or when the gas is to be passed into a gasholder for distribution to several engines, or to heating apparatus, there is an exhauster to draw gas from the plant and deliver it into a holder.

It took a long time to perfect the details of this plant, but one for 300 H.P. was started in October, 1908, at the works of Messrs. Kenrick & Sons, of West Bromwich, and has been working regularly ever since. The results were so satisfactory that in October, 1909, they started a second plant of this type for 700 H.P., and both plants are now serving 13 gas engines which were previously worked with anthracite pressure gas. The author has not an analysis of the gas made in the smaller plant, but in the larger one the percentage was as follows: Carbon monoxide 23·9, carbon dioxide 7·2, hydrogen 16·0, methane 1·0, nitrogen 51·9. The calorific power of the gas is nearly as high as that of gas made with anthracite in an ordinary suction plant. The fuel used at West Bromwich had the following composition: Fixed carbon 55 per cent., volatile matter (other than moisture) 30, moisture 8, ash 7, calorific value 13,400 B.Th.U. per lb. The coal costs 8s. a ton delivered, as against 23s. for anthracite. On an average of several months the consumption of bituminous coal was about the same as with anthracite—namely, about 1 lb. per indicated horse-power-hour—including all stand-by, cleaning and starting losses. The gas has no tar when it leaves the producer, and none is found in the scrubbers or overflow water; and Messrs. Kenrick have stated that the gas from the bituminous coal is as clean as the anthracite gas previously used. They clean the engine valves only once in about three months.

Among other plants of this type in use Messrs. Faire Brothers, of Leicester, are now working one for 400 B.H.P., and they find that their engines work as well with it as with the anthracite plant they previously used. In their case they use a coal of the following composition when dried at 212° F.: Fixed carbon 57·90 per cent., volatile matter 37·50, sulphur 1·0, ash 3·60, moisture 11·10 per cent., calorific value 12,100 B.Th.U. per lb.

At first the author thought that these plants would not be suitable for small powers, but more recently he has had a 30 H.P. suction plant of this type working regularly for about eight months, and it has given no more trouble than an ordinary suction plant working with anthracite or coke. The engine valves were not cleaned for five months.

M. Bontillier & Cie., of France, have a producer in which bituminous coal is forced into the bottom of the fire by means of a screw feed, and as the producer is worked with an up-draught from a blower the tarry vapours distilled off at the bottom pass through the incandescent fuel above. Power is, of course, required to send in the coal, and the rate of feed must be regulated to suit the rate of consumption. The author has seen a plant of this type working well with semi-bituminous Belgian coal, containing 12 to 13 per cent. volatile matter. He does not know what the result would be with English coal, which usually contains not less than 30 to 35 per cent. of volatile constituents.

In conclusion, the author points out that for engine work the stand-by loss of a steam boiler is much greater than that of a gas producer, and the explanation is not far to seek. For a given horse-power the producer is much smaller, and has far less radiating surface than a boiler, it has no water in it to be heated, and in a few minutes it can be worked up to its maximum production after standing almost any length of time. With a boiler, except in the vertical or portable type, there is a large amount of external brickwork to be heated, and there is a considerable quantity of water, even in the tubular type. When the boiler is standing the water and the brickwork lose heat, and not only more time but more fuel is required to make up this loss than in the case of a gas-producer. Doubtless the heat efficiency of a good boiler is high when it is working to nearly its full capacity, but the reverse is the case when it is standing. Table III. gives some comparative results.

THE REACTANCE OF ASYNCHRONOUS MOTORS WITH SQUIRREL-CAGE ROTORS.

BY J. REZELMAN.

Summary.—The leakage reactance of a 2 pole 50 H.P. induction motor is analysed. The rotor winding is found to exert no magnetising effect upon the end coils of the stator winding. The losses on short circuit are determined for various frequencies.

In the preceding article* the reactance of asynchronous motors with *wound rotors* has been analysed; let us now determine the leakage of a motor with *squirrel-cage rotor*.

Three phase motor 50 H.P., 2 poles, 50 ~, 3,000 revs., 380 volts between phases.

Stator. ϕint = 265 mm. $\tau = 417$ mm.
$l = 180 - 2 \times 7{\cdot}5$ mm. $l_i = 170$ mm.
slots = 24 (20 × 40) $t_s = 34{\cdot}7$ mm.
$S_s = 9$ $p = 1$ $q = 4$, Fig. 1.

Rotor Single air gap $\delta = 1{\cdot}5$ mm.
slots = 41 (7·5 × 23) $t_r = 20{\cdot}3$ mm.
$S_n = 1$ $p = 1$ $q = 6{\cdot}85$, Fig. 1.

The stator is wound *per pole*.

Phase I. $l_s = 670$ mm. $l_{sa} = l_{s'b} = 360$ mm.
Phase II. $l_s = 850$ mm. $l_{sa} = l_{s'b} = 540$ mm.
Phase III. $l_s = 955$ mm. $l_{sa} = l_{sb} = 645$ mm.

$U_{sa} = U_{sb} = 150$ mm.; $l_{sc} = 310$ mm.; $U_{sc} = 380$ mm. for phases I., II. and III.

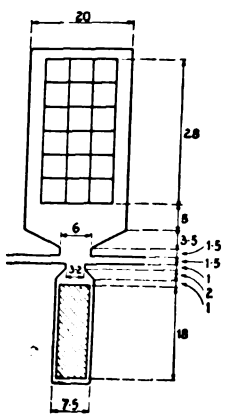

FIG. 1.

Auxiliary turns (20) had been placed in the middle and following l_s of *Phase II.*, Fig. 2; the E.M.F. induced in the end coils of this phase will then be $\frac{72}{20} = 3{\cdot}6 \times$ that induced in the 20 auxiliary turns.

Complete tests have been carried out:—

(A) With end-shields, without rotor.
(B) With end-shields, with rotor.
1. Single phase per phase.
2. Single phase two phases in series.
3. Three phase.

The experiments have given the following results.

* THE ELECTRICIAN, March 10, 1911.

We establish that the E.M.F. induced in the auxiliary turns, and hence in the end connections, is the same *with* or *without* rotor. As shown by Fig. 2, the end rings of the squirrel cage are in fact too distant from the stator coils to exercise a demagnetising influence on them, and the induction coefficient A thus retains its value.

Further the experiment three phase (Table III.) shows that, for the same current in phase II., the E.M.F.s induced in the auxiliary coils are the same with the rotor *turning* or *fixed*.

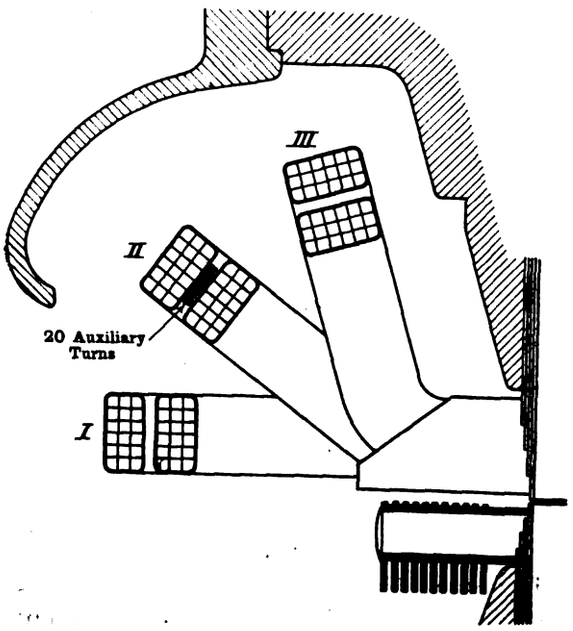

FIG 2.

The mutual induction between the end coils of the different phases is about $\frac{3·5}{2·7}=1·30$.

The reactance is independent of the position of the rotor relatively to the stator; there is thus no formation of a *common* field of a high order, which results from the property of the squirrel-cage winding to create in the air gap a repetition of the M.M.F. corresponding to that of the stator. It follows then that the reactances x_{sn} and x_{sk} *per phase* must be the same with single phase *one phase only* as for *two phases in series*; the total reactances per phase can only *differ* by the augmentation of x_{ss} due to the mutual induction between the *end coils*.

The experiments on single phase, one phase only, of such a motor (Table I., with rotor) thus enable us to determine directly the mutual induction between the end coils by measuring the E.M.F.s induced in the open phases. It is to be noted that the reactance *without* rotor is higher than *with* rotor:—

On single phase, one phase only, by 8 per cent., and on single phase, two phase in series by 15 per cent., the difference

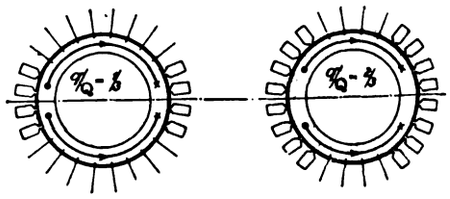

FIG. 3.

between the 8 and 15 per cent. being due to the mutual induction between the end coils.

(A.) *Without Rotor.*

One Phase only: $Q=12$, $q=4$

by calculation $\lambda_n=1·89$ and $\lambda_k=5·78$

whence $x_{sn}+x_{sk}=0·275w$.

The values for the induction coefficient A of the end coil are found to be

$A_I = 0·274$

$A_{II} = 0·272$

$A_{III} = 0·241$

Two phases in series: $Q=12$; $q=8$

$\lambda_n=1·89$ and $\lambda_k=6·85$

whence $x_{sn}+x_{sk}=0·60w$.

The coefficient of mutual induction between the end coils of phases I., II. and II., III. is 1·29, whilst that for I., III. is 1·21.

(B) *With Rotor.*

One phase only. Stator: $Q=12$, $q=4$ ..... $q/Q=\frac{1}{3}$

Rotor: $Q=20·5$, $q=6·85$..... $q/Q=\frac{1}{3}$

by calculation $\lambda_{n_1}=1·87$; $\lambda_{n_2}=2·46$,

$\lambda_{k_1}=0·835$; $\lambda_{k_2}=1·18$,

whence $x_{sn}+x_{sk}=0·167w$.

Digitized by Google

We know the value of the reactance of the end coils of the stator (determined above, in (A)), and thus find for the end rings of the rotor

$$x_{rII}=0{\cdot}068w.$$

From an inspection of Fig. 3 it is apparent that the two rings in reality represent a winding *per pole*.

By taking l_r equal to the arc corresponding to the middle of the slots

$$l_r=l_{ra}=l_{rb}=\frac{\pi\times 236}{2}=370 \text{ mm.}$$

and

$$U_{ra}=U_{rb}=156 \text{ mm.}$$

Hence

$$\lambda_{ra}=\lambda_{rb}=0{\cdot}46\times 2\left(\log\frac{2\times 370}{156}+A\right)=0{\cdot}63+0{\cdot}92A$$

and

$$L_{ra}+L_{rb}=2\times\frac{12{\cdot}5\times 50\times 18^2}{1\times 2\times 10^8}\,37(0{\cdot}63+0{\cdot}92A)=0{\cdot}0473 +0{\cdot}69A=0{\cdot}068,$$

whence $A=0{\cdot}30$ and $R=1{\cdot}44$.

Two phases in series.

Stator ..... $Q=12$, $q=8$... ..... $q/Q=\frac{2}{3}$

Rotor ..... $Q=20{\cdot}5$, $q=13{\cdot}7$ ..... $q/Q=\frac{2}{3}$

$$x_{sa}+x_{sb}=2\times 0{\cdot}167=0{\cdot}334w.$$

In a similar manner the reactance of the rotor end rings is found to be $x_{rII}=0{\cdot}115w$, that is to say, $\frac{0{\cdot}115}{0{\cdot}068}=1{\cdot}7$ times the value for *one phase only*.

Other experiments have been carried out on this motor; measurements have been made of the watts absorbed when a

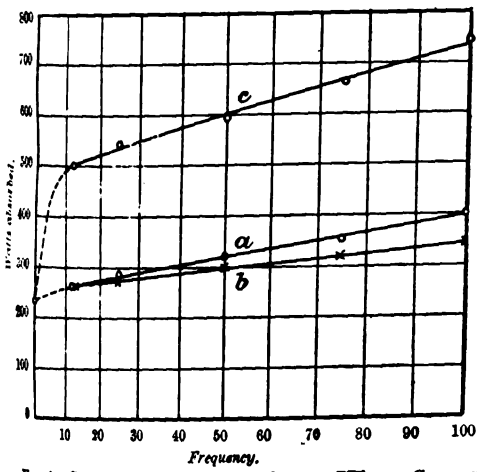

FIG. 4.—SINGLE PHASE, PHASES II. AND III. IN SERIES; CURRENT, 45 AMPERES CONSTANT.

47·1	45	596	50·0	
91·3	45	740	100·2	(*c*) With rotor and with end-shields.
66·5	45	668	75·0	
26·2	45	542	25·0	

The losses have been plotted as a function of the frequency (Fig. 4). By comparing (*b*) and (*c*) the losses in the rotor at $50\sim$ are found to be: $596-300=296$ watts and at $12{\cdot}5\sim$ the losses are only $500-260=240$ watts. This diminution with the frequency explains why the slip of an induction motor (especially with a rotor wound with bars of large section) is smaller than the value calculated from the watts measured on short-circuit. In the rotor of a three-phase motor, the frequency of the current corresponding to the slip is so small that the corresponding supplementary losses are negligible.

For the same reason the permeance of the rotor may vary with the speed, since it contains magnetic material subjected to induction. On short-circuit, with the rotor fixed, the high-frequency impedes the magnetisation, whilst at normal speed it may be sufficiently reduced to permit of the free formation of the lines of force.

PROTECTION OF ELECTRICAL TRANSMISSION LINES.*

BY E. E. F. CREIGHTON.

Summary.—The object of this Paper is, primarily, to describe a new method of protecting line insulators against arcs to earth and the consequent surges which accompany such accidental arcs. The apparatus for accomplishing this is described, and its scope of application and limitations pointed out. Secondly, to point out the trend of the developments in line protection, to record some experimental data relating to the problem of line protection and to speculate on certain lightning effects.

In the past, considerable attention has been given to the protection of electrical apparatus. For the protection of medium and high-tension apparatus the aluminium arrester has had sufficiently long use to attest its undoubted value. There has, however, been no type of arrester developed suitable to the protection of line insulators, and, judging from our present knowledge of lightning phenomena, there is little prospect of such a development being made. In general, arresters are not suitable for line protection, and there is nothing yet offered which does not involve an interruption of service when an accidental arcing to earth takes place, as well as permitting surges of high frequency and of considerable energy in the system.

The problem of line protection may, for present purposes, be divided into two parts: (1) The suppression of the arc that follows a lightning discharge over an insulator. (2) The prevention and suppression of short-circuits between phases (this phenomenon occurs relatively rarely). This Paper has to do mostly with the first division of the problem, and a three-phase circuit only is considered.

If one phase becomes accidentally earthed, its potential will be reduced to the effective potential drop along the arc. If this phase has attached to it a single-phase switch which will connect it to earth, the wire will be reduced to earth potential, and the arc around the insulator will be extinguished by lack of potential—*i.e.*, shunted out. The insulator reassumes its normal condition of insulation as soon as the arc vapours are cooled below the temperature of conduction, in general taking but a small fraction of a second. If the earthing switch is now opened, the circuit will assume again its normal condition of equality of potential of each phase above earth without interrupting the service.

Selective Relay.—Between the phenomenon of the arcing earth and the closing operation of the single-pole switch there must be an intermediate device which picks out the phase that is earthed and closes the proper relay to operate the single-pole switch.

In Fig. 1 the circuit connections are shown for an electrostatic selective relay. Three insulators are set at angles of 120 deg., facing each other in a horizontal plane. The pin of each insulator is insulated by being fastened to another insulator and connected respectively to the three phases. The electrostatic fields produced at the heads of these insulators act mechanically on three earthed aluminium plates placed in front of them. These three aluminium plates are connected together by three light radial rods. At the centre these rods connect to the bottom of a pendulum, pivoted at the top so that it can swing in any angle away from the vertical. This gives a balanced mechanical system which remains stationary for all voltages so long as they are equal. If, however, as in the case assumed, one phase (C) is earthed, the electrostatic force on the corresponding aluminium plate is weakened and on the other two plates strengthened. The result is that the pendulum moves over against the contact, marked SC in Fig. 1. Making this contact operates the trip coil on a single-pole oil switch. This relay is easily adapted to all high voltages, but the forces drop off so much for low voltages that it is then found

* Abstract of a Paper read before the American Institute of Electrical Engineers.

Digitized by Google

necessary, so far, to resort to potential transformers and electromagnetic coils.

Fig. 2 shows a diagrammatic sketch of the connections of an electromagnetic selective relay. Three potential transformers, TA, TB and TC, are connected in Y and the neutral is earthed. The secondary of each is connected directly to a solenoid. The solenoids stand in a vertical position, and each has hung over it a core of iron suspended to a three-arm lever pivoted at the centre C. Just above each lever is a contact point which, when closed, trips the single-pole earthing switch corresponding to the phase. The operation is the same in principle as the electrostatic relay.

The safety auxiliary devices consist of damping resistance in connection with the switch, interlocks between the three independent single-phase switches, and an interlock on the selective relay, as an extra safeguard against closing two single-phase switches at once.

Every circuit containing inductance and capacity is subject to electric oscillations when an arc takes place in any part of the circuit. Where capacity predominates the arc current is seldom continuous. Resonance implies repeated impulses or oscillations. If the arcing earth has a resistance in series equal to the critical value given by the equation $R=2\sqrt{L/C}$, each single impulse will die out without oscillation. Even if the resistance is only one-fifth the above value the oscillation disappears quickly. The accidental arc around an insulator is extinguished as quickly as possible by the switch; it is then necessary to extinguish the arc to earth in the switch as it opens. To eliminate the dangers from oscillations, damping resistance is placed in the switch pot. This resistance is thrown in series as the switch rod moves out (Fig. 3).

The three single-pole switches of the suppressor are provided with a common interlocking device operated by a solenoid, which prevents any two switches from getting in the closed position simultaneously, and thus causing a short-circuit.

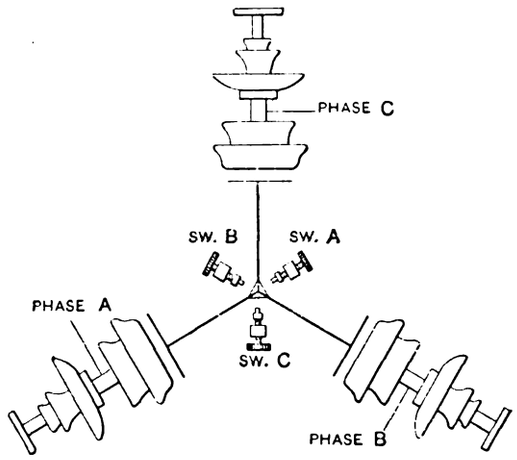

FIG. 1.—DIAGRAM OF ELECTROSTATIC SELECTIVE RELAY.

As a further precaution against accidental short-circuits in the switches, the natural conditions of construction of the relays make it impossible to close two trip coils simultaneously. The three contact points on the selective relay, which are connected to the trip coils, are so widely spaced that the pendulum cannot swing against two at the same time.

So far an arc around an insulator has been considered. In this circumstance the protecting switch closes, and opens automatically a fraction of a second later. If, on the other hand, the insulator is defective and punctures, the line potential will re-establish an arc to the iron pin. This will cause the switch to close again. This second time it is locked shut until the attendant opens it by hand. This second stroke lock comes into action only if the switch starts to close the second time immediately after the first time. In other words, if the switch stays open for a fraction of a second after the first stroke, the second stroke lock becomes inoperative. With the arc shunted out, the dangers from arcing earth surges are avoided. The system can continue to operate with a metallic earth until the fault is located and the faulty line cut out. The chief source of danger in such operation is in the possibility of a second stroke of lightning establishing another arcing earth on another phase before action is taken to clear the feeder.

Cable Systems.—When the insulation of a cable fails the damage is permanent. The distance from the conductor to the metallic sheath is so small that the normal impressed difference of potential is sufficient to re-establish an arc, even if it were automatically extinguished. It is seldom indeed that an accidental arc is established in a cable from conductor to conductor. The usual case is a failure of one conductor to the sheath. When this occurs there is nothing to be done but earth the faulty phase to the sheath, and thus extinguish the arc. This simplifies the switch operation, for it is necessary for the switch to close once and stay closed until the feeder has been cleared.

As to the safety of operation with one phase earthed, the factor of safety on the other two phases is somewhat reduced by the fact that their potential is increased by 73 per cent., but this should not produce a serious strain. There is no arc to produce high frequency, therefore there is left to consider the possibility of obtaining resonance in any part of the circuit at the frequency of the generator and of such harmonics as may be prominent. The capacity current flowing into the two non-earthed phases must pass through the inductance of the generator and connecting transformers. Taking into account the possible wide variations of inductance and capacity in all systems, one is forced to acknowledge a chance of obtaining resonance with a phase metallically earthed, but resonance in itself has no terrors. The increment of energy in the resonant surge is always small relative to the energy given out even by a small transformer. If a transformer, for example, is loaded even with a few lamps, the resonant potential will be held down by the absorption of the energy of the surge in the lamps. If, on the other hand, the transformer is not loaded and it is in a condition of resonance, its resonant energy will be absorbed by some parallel loaded transformer. When the possibility of resonance internally between coils of a transformer is considered it can be stated positively, I believe, that there is none. Also the natural frequency of a local surge between coils is invariably too high to resonate with the frequency of the impressed potential from the generator.

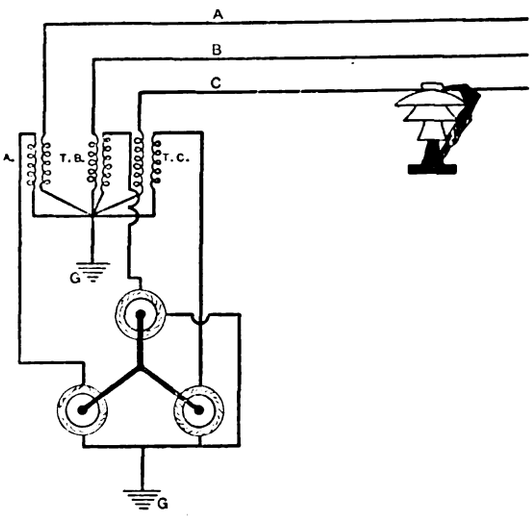

FIG. 2.—DIAGRAM OF ELECTROMAGNETIC SELECTIVE RELAY.

As a further and final safeguard against possible rises in resonant voltages when a phase is metallically earthed, a reasonable amount of resistance can be kept in the circuit to earth. This resistance will absorb the resonant energy if it appears. There is a limit to the amount of resistance on account of the permissible IR drop. This must not be such as to re-establish the arc at the fault.

Tests of the Arc Suppressor.—Tests were made on a line of the Schenectady Power Co., 21 miles long. The delta potential is 33,000 to 35,000 volts at 40 cycles. An insulator was made defective by meansof two wires from cap and pin respectively, which were held within sparking distance of each other, and the gap length around the insulator was shortened until the arc would, when started, hold continuously. A number of oscillograph records are given in the Paper.

The best location of the arc suppressor is usually at the power house, although cases may arise where some central switching station gives greater convenience. To get figures on the limitation of a device, the line constants of a 45-kv. system are used as a basis. The Y potential to earth is normally 26 kv., the charging current about 0·15 amperes per mile, the inductive resistance about 0·75 ohms per mile, and the impedance 0·86 ohms per mile at 60 cycles. Assume one phase earthed at the power house by the operation of its protecting switch, caused by an insulator arcing over at a distant point. The potential of this phase at the generator is zero, but the line wire is not zero throughout its entire length. There may be a considerable potential at the faulty insulator. This is found by multiplying the total charging current in the line by half the impedance.

Since all the treatises on the subject of line capacity assume a

Digitized by Google

normal condition of no phase earthed, the electrostatic capacity to earth can be and is neglected. The author, therefore, considers at some length the capacity of a system with one phase earthed. Earthing a phase of an electrical system has about the same electrical effect as the mechanical shifting of a cart wheel axis from the centre of the wheels to some eccentric point out near the rim of the wheels. At a high speed the cart would then progress by jumps. If the earth is arcing, the electrical conditions correspond to a flat wheel on the cart. Every time it drops it bumps and sets up vibrations or oscillations throughout the body or system.

The remainder of the Paper is a general discussion of protective problems. The author concludes as follows: There are numerous minor problems, but the main problems which are to be solved before absolute continuity of service can be attained are: Protection against direct strokes of lightning, the suppression of short-circuits, the suppression of internal surges and the prevention of malicious or wilful interference. More or less satisfactory solutions of all but the last-mentioned problem are in sight. Will the demand for great continuity of service warrant the expense involved in getting such service? A collection of a considerable amount of data shows conclusively on analysis that the greatest number of interruptions in lightning infested localities is due directly and indirectly to the single arcing earth around an insulator, or in cable systems to a single puncture from one phase to the cable sheath. The arcing earth

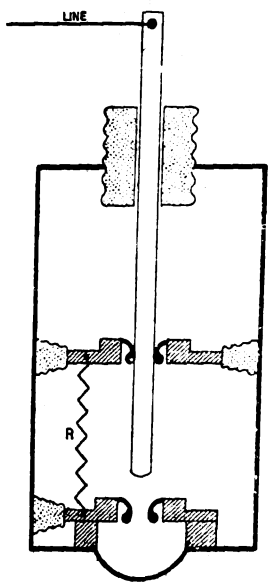

FIG. 3.—DAMPING RESISTANCE IN THE SWITCH POT.

suppressor, backed up by aluminium arresters, will prevent interruption of service and damage to apparatus in the majority of these cases. This improvement should in general bring the service above the existing standards or requirements. It may be possible to meet the higher demands in the future as they grow.

INSTITUTION OF ELECTRICAL ENGINEERS.

At the annual general meeting of this Institution, which took place on Friday last, the president, Mr. S. Z. de Ferranti, read the report of the Council, an abstract of which is given below. The honorary treasurer, Mr. R. Hammond, made a statement relating to the finances of the Institution. The adoption of the report was then moved by the President and seconded by Mr. J. F. C. Snell. A number of resolutions of thanks were then put to the meeting and carried. These included: "The Honorary Secretaries of the Local Sections and the Secretaries Abroad," proposed by Mr. J. F. C. Snell and seconded by Mr. L. Gaster; "Mr. Robert Hammond for his services as honorary treasurer," proposed by Major W. A. J. O'Meara and seconded by Mr. Sidney Sharp; "The Honorary Auditors," proposed by Mr. W. Clark and seconded by Mr. R. W. Hughman; "The Honorary Solicitors," proposed by Mr. R. A. Chattock and seconded by Mr. S. Rentell.

The President then announced that as no further nominations had been received the Council for the next session would be that already circulated to members (the list was given in THE ELECTRICIAN of April 28th). On the motion of Mr. W. Clark, seconded by Mr. R. W. Hughman, Mr. Sidney Sharp and Mr. H. Alabaster were elected honorary auditors for the forthcoming session. The meeting then adjourned.

The following is an abstract of the report of the Council:—

Growth of the Institution.—Since the last annual general meeting applications for admission into the Institution have been received from 502 persons, of whom 20 have been elected as members, 193 as associate members, 32 as associates, and 221 as students. 100 foreign members, 58 associate members, and 14 associates have been transferred to the class of members, 12 associates and 111 students to the class of associate members, and 14 students to the class of associates.

Members Deceased.—Among well-known members who have died since the last annual general meeting are Sir John Aird, Bart., Mr. G. Byrg, Mr. B. T. Ffinch, C.I.E., Mr. Geo. Flett, Sir W. B. Gurdon, C.B., K.C.M.G., Sir J. Clifton Robinson, and Mr. J. Wetzler.

Meetings and Papers.—During the past session 17 general meetings, one special general meeting, and 21 council meetings have been held. The usual standing committees have met regularly throughout the session, and several occasional committees appointed by the council for the consideration of special matters have also met with, the total number of committee meetings held during the session being 109. There have been 50 meetings of local sections, viz., 7 at Birmingham, 7 at Dublin, 6 at Glasgow, 11 at Manchester, 12 at Newcastle, and 7 at Leeds and Sheffield. The annual dinner of the Institution took place at the Hotel Cecil, London, on February 2, 1911. Annual dinners and other social functions were held at Birmingham, Dublin, Glasgow, Leeds, Manchester, and Newcastle, which were well attended by members and guests, and at which several members of Council were present.

Scholarships.—The Council have awarded Salomons Scholarships of the value of £50 each to Richard Michael Clark, of University College, and to Edward M. Teare, of the Finsbury Technical College; and a David Hughes Scholarship of the value of £50 to Francis Lewes Otter, of the Central Technical College.

Premiums.—The list of premiums for Papers has been revised and in future premiums will be awarded in accordance with the list shown below. In considering Papers, those published in the "Journal" without being read at a meeting, will not, after this year, be considered separately from those read at meetings.

Name.	Subject.	Value.
		£
Institution	Any	25
Ayrton.....	Practical Applications of Electricity.....	10
Fahie	Telegraphs and Telephones.....	10
John Hopkinson .	Design and Construction of Electrical Machinery	10
Kelvin	Scientific Research	10
Paris	Any	10
Webber	Military and Naval Applications of Electricity.....	10
Extra Premium ...	Any	5

The following premiums for Papers have been awarded by the Council this year. In accordance with precedent, in deciding upon these awards the Council have not taken into account Papers contributed by present members of Council. The Institution premium, value £25, to Sir R. A. Hadfield, F.R.S., and Prof. B. Hopkinson, F.R.S., for their Paper, "The Magnetic Properties of Iron and its Alloys in Intense Fields." The Ayrton premium, value £10, to Mr. H. T. Harrison, for his Paper, "Street Lighting by Modern Electric Lamps." The Fahie premium, value £10, to Mr. Donald Murray, for his Paper, "Practical Aspects of Printing Telegraphy." The John Hopkinson premium, value £10, to Messrs. A. P. M. Fleming and R. Johnson, for their Paper, "Chemical Action in Winding of High-voltage Machines." The Paris premium, value £10, to Mr. W. T. Taylor, for his Paper, "Modern Long-distance Transmission of Electrical Energy." An Extra premium, value £5, to Dr. E. Rosenberg, for his Paper, "Control of Electric Winding and Hoisting Engines." A premium, value £5, to Mr. C. C. Hawkins, for his Paper, "The Theory of the Static Balancer." Students' premiums: A Students' premium, value £10, to Messrs. G. W. P. Page and G. J. Scott, for their Paper, "Single-phase Commutator Motors, especially the Latour Winter Eichberg Type." A Students' premium, value £5, to Mr. Hugh C. May, for his Paper, "Notes on the Design and Construction of Dry-core Lead-covered Telephone Cables." A Students' premium, value £5, to Mr. Allan Monkhouse, for his Paper, "Recent Electric Locomotive Practice and the High-tension Direct-current Railway System." A Students' premium, value £5, to Messrs. R. C. Plowman and E. F. Hetherington, for their Paper, "Exhaust Steam Turbines." A Students' premium, value £5, to Mr. A. R. Stelling, for his Paper, "Organisation and the Reduction of Manufacturing Costs."

Scottish Local Section.—At the end of last March the Council granted a request from members residing in Scotland that the name of the Glasgow Local Section should be changed to Scottish Local Section, and that it should include all members residing in Scotland.

Students' Sections.—At the opening meeting of the session an address to the students was delivered by Mr. C. H. Wordingham. Ten meetings of the Students' section have been held, at which Papers were read and

Digitized by Google

discussed. The Students' Committee organised a visit to Birmingham in 1910, when the following works and places of interest were visited: The British Thomson-Houston Co., Rugby; Messrs. Belliss & Morcom; Messrs. Humber, Coventry; the Electric Construction Co. and Corporation tramways, Wolverhampton; Messrs. Alfred Hickman, Bilston; the Birmingham University; Messrs. Siemens Bros. Dynamo Works, Stafford; the General Electric Co.; the Birmingham Corporation generating station; and the Sandwell Park Colliery, to all of whom the cordial thanks of the Institution are due. The annual dinner of the Students' Section, held on February 18, 1911, was well attended. The Glasgow and Manchester Students' Sections have each completed a successful session, having held six and nine meetings respectively. Visits were made to various works by the kind permission of the firms concerned.

The Institution Building.—During the last week of June, 1910, the offices were transferred to the Institution building from 92, Victoria-street, Westminster, S.W. The structural alterations were completed and the lecture theatre, the common room, and the library were ready for use on the occasion of the delivery of the Inaugural Address of the President, on November 10, 1910. The Council believe that the influence of the Institution on the interests of the electrical industry can be greatly extended by the practice of gathering together various kindred institutions and associations. With this in view the Council have granted the use of the lecture theatre and of meeting rooms to a number of engineering bodies, among others the Institution of Post Office Electrical Engineers, the Municipal Electrical Association, the Faraday Society, the Röntgen Society, the National Electrical Manufacturers' Association, the National Electrical Contractors' Association, the Associated Municipal Engineers of Greater London, the Junior Institution of Engineers, and the Society of Engineers. The use of the lecture theatre has also been granted to the University of London for the delivery of a course of lectures on "The Application of Hyperbolic Functions to Electrical Engineering Problems," by Dr. A. E. Kennelly, of Harvard University, from May 29 to June 2, 1911. The Council desire to draw the attention of members to the common room which is available for use as a reading and smoking room, and for appointments and interviews. It is also generally possible for members to obtain the use of one of the committee rooms, especially in the morning, by applying to the secretary a few days in advance.

The British Electrotechnical Committee.—The British Committee for 1911 is constituted as follows:—Mr. A. Siemens (*president*), Col. R. E. Crompton, C.B., Mr. W. Daddell, F.R.S., Mr. K. Edgcumbe, Mr. S. Z. de Ferranti, Sir John Gavey, C.B., Dr. R. T. Glazebrook, C.B., F.R.S., Mr. R. Kaye Gray, Mr. R. Hammond, Mr. R. W. Hammond, Mr. C. Le Maistre, Prof. T. Mather, F.R.S., Mr. W. M. Mordey, Mr. H. W. Miller, Major W. A. J. O'Meara, C.M.G., Mr. W. H. Patchell, Sir W. H. Preece, K.C.B., F.R.S., Lord Rayleigh, Dr. A. Russell, Mr. J. F. C. Snell, Dr. S. P. Thompson, F.R.S., Mr. A. P. Trotter, Mr. E. B. Vignoles Mr. C. H. Wordingham, and Mr. P. F. Rowell (*secretary*). During the last session progress has been made with the preparation of the list of electrotechnical terms. The nomenclature sub-committee have under consideration the German list of terms submitted at the Brussels Conference, and definitions are being prepared for the terms not already in the English list. On August 8, 9, and 10, 1910, an unofficial Conference, arranged by the Belgian Electrotechnical Committee and presided over by Prof. Eric Gérard, Director of the Institut Electrotechnique Montefiore at Liège, was held in Brussels in the Council Chamber of the Ministry of the Belgian State Railways. The British Committee were represented by Mr. Alex. Siemens (*president of the Committee*), Mr. W. Daddell, F.R.S., Mr. K. Edgcumbe, Mr. Robert Hammond, Major W. A. J. O'Meara, C.M.G., Mr. W. H. Patchell, and Mr. P. F. Rowell (*secretary*). The Conference discussed a number of propositions in reference to nomenclature, symbols, the direction of rotation for vectors, and the rating of electrical machines; and eventually passed certain informal resolutions embodying suggestions on these subjects with a view to their being considered by the various committees and, if approved, ratified at the next meeting of the International Electrotechnical Commission which will be held in Turin in September, 1911. At the conclusion of the sittings the members of the Conference were entertained by the Belgian Committee to a number of functions and visits to places of engineering interest at Charleroi, Liège and Antwerp.

Wiring Rules.—The revised edition (the sixth) of the Wiring Rules, which was published on May 1, has been prepared to meet as far as possible the developments of the electrical industry. In preparing this edition the Council have had the assistance of some of the principal Fire Offices, the Incorporated Municipal Electrical Association, the Electrical Contractors' Association, and the Cable Makers' Association, all of whom were represented on the Committee who carried out the work of revision on behalf of the Council. The figures in the table relating to the current-carrying capacities of conductors are based on an exhaustive series of tests carried out at the National Physical Laboratory on the temperature rise of conductors. The new rules have been adopted by 49 fire offices, and they are accepted as standard practice and their use recommended by 232 supply authorities.

Model General Conditions for Contracts.—A draft revision of the model general conditions for contracts has been completed, and the clauses are at present under further consideration with a view to their being made acceptable to a larger number of interested bodies.

Electricity in Textile Mills.—The Committee appointed to consider this subject have had several meetings.

Street Lighting Specification.—The Council have appointed a committee consisting of representatives of this Institution, and of representatives nominated by the Councils of the Institution of Gas Engineers, the Institution of Municipal and County Engineers, and the Illuminating Engineering Society, to consider the preparation of a specification for street lighting to be issued jointly under the auspices of the various interested bodies.

Kelvin Lecture.—The third Kelvin lecture will be delivered next autumn by Dr. R. T. Glazebrook, C.B., F.R.S. The subject will be Lord Kelvin's work in connection with fundamental units, and to a considerable extent the lecture will be experimental.

Examinations for Associate Members.—The Council have decided to hold examinations of candidates for election and transfer to the class of associate members after January 1, 1913. Candidates will be required to pass—(*a*) An examination in general knowledge, and (*b*) an examination in one of the four special subjects: (1) Power, lighting and traction, (2) telegraphy, (3) telephony, (4) electrochemistry and electrometallurgy. The questions will be set with the object of showing that the candidates possess a good general education and a reasonable amount of fundamental knowledge in one of the branches of the profession. Due consideration will also be given to the practical side of electrical engineering, and moreover the candidate's admission or rejection will not depend solely on his answers to the papers set, but these will be considered in conjunction with the candidate's practical experience, which must be in accordance with the requirements of the articles of association. In lieu of examination, candidates will be allowed to present a thesis, Paper, or other contribution to electrical knowledge, and they will be liable to be examined orally by the examiners on the subject presented. Certain degrees or diplomas will procure exemption from the whole or part of the examination, and the Council will have power in approved cases to grant exemptions. The complete details are under consideration with a view to publication at an early date.

Examinations for Students.—The Council have decided that from January 1, 1913, candidates for election as students shall be required to pass or to have passed either the matriculation examination of one of the British Universities or some school-leaving or other equivalent examination which shall satisfy the Council of the candidates' general education. In view of the number of existing examinations, which is already very large, the Council deemed it wise not to conduct a special examination. Full details will be available at an early date.

Journal.—It has been felt for some time that it would be desirable to make arrangements for a more frequent publication of the "Journal," so as to ensure that members shall receive promptly full and accurate reports of the Papers read and of the discussions at the meetings of the Institution and of the local sections, and the Council have accordingly given instructions for a report to be prepared on the subject. The value of the lectures and of the Papers and discussions at the informal meetings mentioned elsewhere in this report would be greatly increased by early distribution among the members as a whole, and especially those residing abroad or at a distance from the place of meeting. It is also hoped that the result would be to render the "Journal" more efficient as a means of communication between the Council and the members. The advantages of publication at shorter intervals than six weeks (as under the present system) are so obvious as not to require mention in detail, but in view of the gross expenditure on the "Journal" which at present stands at £2,040 per annum, exclusive of salaries and cost of office accommodation, and would necessarily be increased by such a change, at least during the first few years, the decision of the Council in regard to this matter will largely be governed by the funds at the disposal of the Institution.

Lectures.—The Council have under consideration the subject of lectures at meetings of the Institution and of the local sections. The lectures would be on electrical subjects or on subjects scientific, economic, financial, or commercial, connected with electrical science or engineering, treated in a general manner, and if possible illustrated by experiments. The underlying idea of the lectures is to bring before the members general surveys treated by authorities who have specialised in their own subjects, the object being to keep the members in touch with those outlying branches of electrical science and engineering which are not usually considered in the Papers read before the Institution, and also to keep members informed of the progress of allied sciences of interest to electrical engineers. The lectures, the matter for which would not necessarily be new, would be published in the "Journal" in short abstract only, and it is not intended that there should be any discussion on them. It is proposed to hold two lectures each session, either on the evenings reserved for ordinary meetings or some other evening.

Informal Meetings.—There are many subjects of considerable interest to a limited number of the members, which for various reasons are not of sufficient importance or of sufficiently general interest for the ordinary meetings of the Institution, and the Council have accordingly under consideration arrangements for informal meetings for reading Papers and discussing matters relating to such subjects. The Papers would be short, so as to leave ample time for discussion. To begin with, it is suggested that four meetings a session be held, which could be increased later if required. A short abstract of the Papers would be published in the "Journal," together with an abstract of the discussions.

Summer Meetings.—It is proposed to consider whether arrangements can be made for holding meetings of the Institution in the districts of the different local sections. Each meeting would last for three or four days, part of the time being given to the reading and discussion of Papers and part to visiting the industries of the particular district.

Subscriptions and Entrance Fees.—The Council feel that the time has

Digitized by Google

now arrived when the development of the Institution, as well as the maintenance of its prestige among the great engineering institutions of the world and the possibilities in the direction of increasing of its usefulness to the profession, make it imperative that the members should contribute higher annual subscriptions and entrance fees. These are at present less than those paid to other professional Institutions of equal standing. This matter has recently been under the consideration of the Council, and at the next revision of the articles of association proposals on this subject will be placed before the members.

Articles of Association.—The committee appointed to consider the alterations required in the articles of association will shortly present their report to the Council.

Benevolent Fund.—The committee of management report that the Benevolent Fund of the Institution shows a satisfactory increase for the past year. On Dec. 31, 1910, the capital account of the fund stood at £3,700, as compared with £3,500 at the end of 1909. The donations to the fund in 1910 include one of £20 from the committee of the Electrical Engineers' ball, and one of £8. 8s. from the "25" club. The Council desire to acknowledge their indebtedness to the generosity of these and other donors and subscribers who have supported the fund. Grants in aid amounting to £51 were made during 1910. The Wilde benevolent trust fund stands at £1,846. 4s. 6d.

General Accounts.—The report of the hon. treasurer, Mr. Robert Hammond, is as follows: The balance carried to the general fund at the end of 1910, being excess of income over expenditure, was £3,053. 0s. 2d., as compared with £3,283. 3s. 11d. for 1909, a decrease of £230. 3s. 9d. In this comparison no account is taken of outlays in connection with the acquisition and structural alteration of the Institution building. The balance sheet sets out the total investments other than the investments of the trust funds. The total assets amount to £102,686. 17s. 6d., against which have to be set liabilities amounting to £42,851. 15s. 10d., leaving as the net assets of the Institution £59,835. 1s. 8d. This amount is almost entirely locked up in the acquisition of the lease of the Institution building, in the structural alterations, and in the expenses incurred prior to occupation. The investments in stocks and shares included in the above appear in the accounts at cost price with a book value of £3,133. 2s. 10d., and their value at the current market prices on April 27, 1911, was £2,864. No alteration has taken place during the year under consideration in the two scholarship trust funds. The Wilde Benevolent Trust Fund has been increased by the investment of an amount of £101. 8s. 6d. transferred from income account, and it now stands at £1,846. 4s. 6d. This fund has been increased during the year by £30. 9s., and stands at £642. 12s., which amount now figures in the accounts as a loan to the building fund, the investments of the fund having all been realised. An overdraft is shown of £816. 6s. This amount has been transferred to the building fund. In consequence of the acquisition of the lease of the Institution building, the fund has been augmented as follows: (*a*) permanently, by transfer of £816. 6s. from the entrance fees fund, and by revenue from subscriptions, donations, and sundry other items, £90 11s. 6d.; (*b*) temporarily by loans, on mortgage from the Economic Life Assurance Society £11,500, from life compositions fund £30. 9s., and from general fund £4,047. 15s. 11d., against which £599. 17s. 11d. has been repaid to the Economic Society on account of existing loans. This makes a net increase of £15,904. 4s. 6d., and the fund now stands at £15,990. 3s. 11d. The general fund has increased to the extent of £3,053. 0s. 2d. during the past year, and now stands at £13,188. 10s. 10d.

Library.—The Council wish to draw the attention of the members to the present arrangement of the library. The whole of the books published since 1880 have been classified, and a subject index is being prepared. The eastern half of the shelves under the gallery contain the classified portion of the books, the bound volumes of the principal periodicals being on the western half of the shelves. The books of the Students Library are on the central shelves above the gallery; 76 new books have been purchased since May, 1910, and 181 books and pamphlets have been presented by members, authors, and publishers. The total number of readers during the past 12 months was 1,024, of whom 47 were non members. The Council have under consideration the question of a lending library and the opening of the library in the evenings.

Museum.—Some of the historical apparatus which has been presented to the Institution is temporarily on view in the glass cases in the library, and a room in the basement has been set apart for the exhibition of other historical apparatus in the possession of the Institution. The apparatus is in process of being sorted and classified.

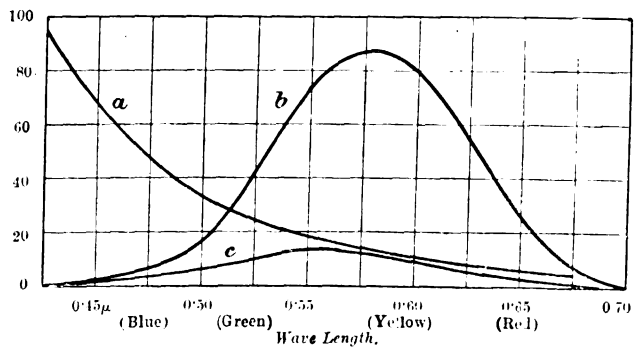
SUBTRACTIVE PRODUCTION OF ARTIFICIAL DAYLIGHT.*

BY H. E. IVES AND M. LUCKIESH.

Most forms of artificial light are very unlike daylight in colour. Incandescent illuminants, such as gas flames and incandescent electric lamps, have the colour of incandescent solids at comparatively low temperatures, such as 2,000° C., while the colour of daylight corresponds more nearly to an incandescent solid at a much higher temperature, about 5,500° C. This means that, when giving the same total illumination, our common illuminants as compared with daylight are deficient in blue light and have an excess of red light. The difference is really very large, and were it not met by a comparatively great power of adaptation in the eye would seriously interfere with our comfort under artificial illumination. Whatever disturbance of vision this change from daylight colour may cause, there is one practical necessity which even the adaptive power of the eye cannot entirely meet—namely, the selection and matching of colours. For certain technical purposes it consequently becomes of importance to secure artificial daylight for use in the absence of the natural article.

One way of doing this is by the use of absorbing media over the lamps. This may be termed the subtractive method, to distinguish from the additive method, the latter being illustrated by the combination of a mercury arc-lamp with tungsten lamps. The nature of the absorption and the method of calculating the resultant loss in efficiency in this subtractive method have been treated elsewhere by one of the present writers.* From that investigation it appears that the transmission of the absorbing screen should be the reciprocal of the relative brightness of the illuminant and daylight at each part of the spectrum. Since that work was done more extensive data have been obtained on the colour value of daylight, and on this basis the necessary absorbing medium to transform tungsten lamplight into "daylight" has been calculated. It should have the transmission throughout the spectrum shown in curve *a* of the diagram herewith. Curve *b* shows the luminosity or brightness distribution in the tungsten lamp; curve *c* the same after transmission through the medium *a*. Comparison of the areas of *b* and *c* shows the resultant candle-power to be 15 per cent. of the original. This is the "daylight efficiency" of the tungsten lamp, and corresponds to about 10 watts per mean spherical candle.

The present Paper is an account of an attempt to obtain coloured glasses and other media approximating to the curve *a*. In the first place, however, attention must be called to the variable character of "daylight." This is of a perfectly definite character; it consists in a very uniform increase or decrease in the intensity of the spectrum toward one end or toward the other. The curves illustrated give a fair average. Again, as to the characteristics of "white" light to make it suitable for colour matching. While a white may be made in which certain colours are entirely missing, such a light



a. Transmission of ideal absorbing medium. *b*. Luminosity curve of tungsten lamp. *c*. Luminosity curve of tungsten lamp through ideal absorbing medium.

TRANSMISSION AND LUMINOSITY CURVES.

would be unsuitable for colour matching. For the ideal white all the colours should be present and in the proportions of daylight. A study of the colours of most natural objects, however, reveals the fact that those colours are very rarely pure isolated spectral hues, but rather long diffused bands of spectral light. As a consequence, a white light consisting of isolated colours may yet possess enough colours to have very little disturbing effect on ordinary coloured objects. Just how many spectral colours should be present is not a matter easily capable of exact statement, but certainly there should at least be three—red, green and blue—and preferably more.

Now we may apply these general considerations, plus some experience and experiment, to the case of artificial daylight and state the following requirements: (1) The total light should appear white. (2) All the spectral colours should be present, but if gaps or irregularities exist in the spectrum the three principal colours—red, green and blue—are necessary.

These requirements fall far short of being exact specifications, but at present it is difficult to see how the various factors to be considered can be reduced to more exact terms. In the work which follows the deviations allowed from the desired character are justified by the experience of the writers as to the actual permissible amount of deviation from the conditions outlined above.

Some sort of blue glass or other medium is called for. Coloured glass is preferable to dyed films or solutions of coloured material, because of its practicability in handling and in permanence. A study of a large selection of samples of coloured glass revealed two shades which might be used—ordinary pot blue, or cobalt blue, and signal green. The first alone transmits blue, an isolated spectral band of

* Abstract of an article in the "Electrical World."

* "Bulletin," Bureau of Standards, June, 1909. (THE ELECTRICIAN, Vol. LXIV., p. 932.)

Digitized by Google

yellowish green, and the deep red. Used alone over a tungsten lamp it gives a purple light, because of the transmitted red. Signal green alone makes the light too green, but it reduces the red that the cobalt blue transmits. A combination of the two appeared promising. Wedges of these glasses were ground and tested for transmission at various thicknesses on the spectrophotometer. From the measurements a combination of the two glasses was chosen which approximates the curve desired. A grave defect of this combination is the pronounced band of yellow-green transmission of the cobalt. In order to reduce this, recourse was had to dyes. A dye—rozazeine—was found by trial which has an absorption band so situated as to cover very well the undesirable yellow-green band of the cobalt glass.

With these two glasses, plus a gelatine film flowed upon one of them and containing a specified amount of dye, an absorbing combination was obtained which produces with a tungsten lamp a very satisfactory approach to "daylight." In the spectrum the total light is "white." No gaps and no bad depressions or humps exist, and the three elevations are in red, green and blue. In short, the conditions outlined above are approximated.

With these glasses a "daylight window" has recently been constructed. This consists of a tin box 16 in. by 12 in. by 20 in. holding six 60-watt frosted-tip tungsten lamps. The bottom of the box consists of the two glasses, one coated with the gelatine film containing the dye, the other a rough glass acting as a diffuser. The whole box rests upon legs 15 in. high. The surface to be illuminated is placed beneath, where an illumination of about 30 ft.-candles is obtained, this value being ample for purposes of colour matching. This window has proved extremely satisfactory on test. The light appears "white" and all colours assume their daylight appearance under it. It has been temporarily used for lighting a desk, and the soft white colour has proved very pleasing. It constitutes a very satisfactory demonstration of the possibility of producing daylight by the subtractive method. The specific consumption is high, being from 10 watts to 12 watts per candle. On the other hand, the first cost is extremely low.

TEST ON 5,000 KW. TURBO-ALTERNATOR.

The tests on the first of the two new 5,000 kw. steam turbo-alternators, which the British Westinghouse Electric & Mfg. Co. is supplying to the Clyde Valley Electrical Power Co., show an even better result than those recently obtained on the 3,000 kw. turbo-alternator, supplied by the same Company to the Bristol Corporation. Particulars of this last-mentioned plant were given in our issue of April 28th. The tests were carried out at the Motherwell power house on April 8th and 9th in the presence of Mr. D. A. Starr, the general manager of the Clyde Valley Electrical Power Co., Messrs. Strain and Robertson, the consulting engineers, and other officials.

The turbines are of Westinghouse latest improved impulse type, which we described in the article referred to above, and are arranged to use high pressure steam at 175 lb. per square inch pressure and 150° F. superheat, both measured at the stop valve. The conditions specified for carrying out the tests were as follows :—

Normal output 5,000 kw., three-phase, 25 cycles, 11,000 volts.	
25 per cent. overload for	6 hours.
Full load for	6 hours.
¾ load for	2 hours.
½ load for	2 hours.
¼ load for	2 hours.

The results of the tests are as follows :—

Output in kilowatts	1,346	2,715	3,902	5,066	6,487·5
Speed, revs. per min.	1,500	1,500	1,500	1,500	1,500
Steam pressure (lb.)	174	176	175	174·5	174·5
Steam temperature (deg. F.)	518	519	542	552	544
Steam superheat (deg. F.)	141	141	164	175	167
Vacuum corrected to 30″ bar.	28·13	28·28	28·58	28·68	28·53
Cir. water inlet temp. (deg. F.).	43·9	43·7	44·0	44·0	43
Cir. water outlet temp. (deg. F.).	48·0	52·6	57·0	60·0	65·5
Total steam consumption (lb.)	24,780	40,130	53,125	65,860	85,880
Steam con., lb. per kw.-hour	18·41	14·78	13·61	13·00	13·24

We understand that Mr. Starr, general manager of the Power Company, the consulting engineers, and the directors have expressed their gratification at the results obtained and at the reduction of the generating costs which has taken place since the turbo-generator was put in commisison.

THE COMET TELESCOPIC MAST AND HOIST.

The efforts of numerous inventors to produce a satisfactory telescopic mast have hitherto been singularly unsuccessful, for, though there is an undoubted market for reliable apparatus of this kind, the difficulties to be overcome are considerable. It is claimed that the Comet mast, which we describe and illustrate herewith, represents an eminently practical piece of apparatus of a robust nature, which is easily portable, which can be rapidly erected, and in which the very simplest mechanical parts are employed.

The mast consists of a series of welded steel tubes of gradually decreasing diameter and thickness, which are adapted to slide telescopically within one another. The novelty of the design lies in the method employed for extending the mast, for which purpose an un-

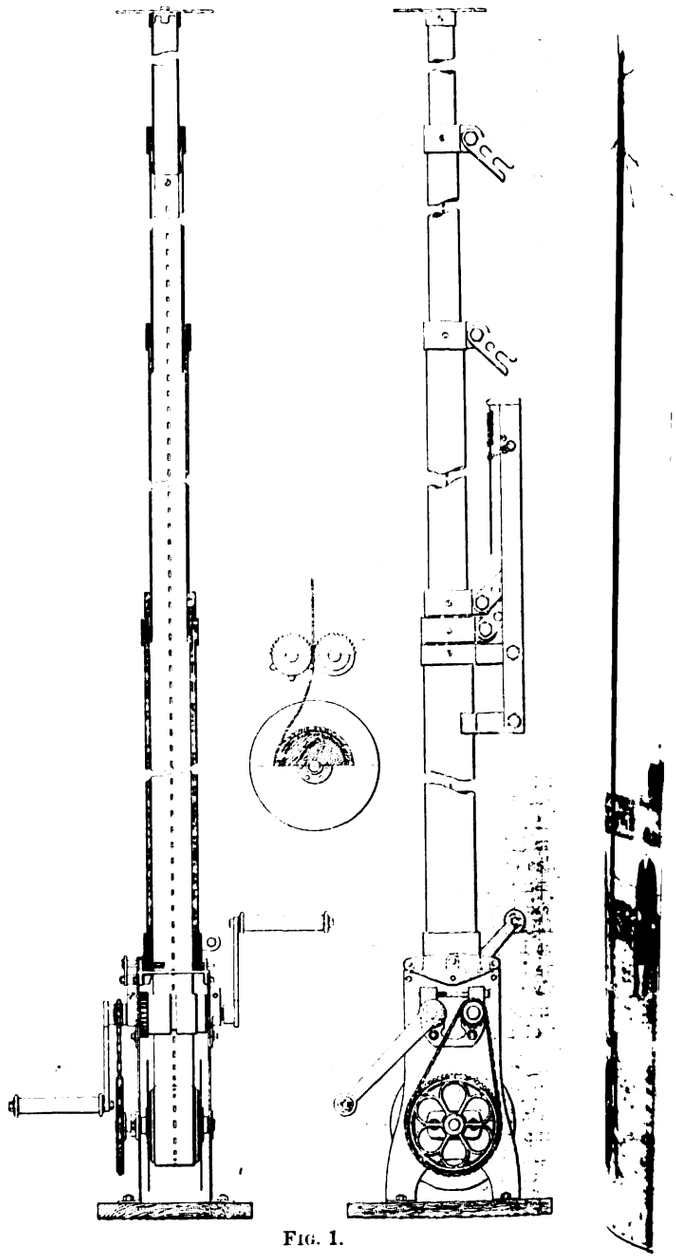


FIG. 1.

tempered perforated steel band is employed. The width of the band follows the internal diameter of the tubes, so that it has a stepped profile as seen in Fig. 1. Within each section the band is a sliding fit, and occupies the full diameter of the circular tube, or, where the tube is of square section for raising heavier loads, the band occupies the full diagonal. As the diameter and the diagonal are respectively the longest lines which can be placed within a circle and square, it is obvious that no further guide is necessary, the band acting as a rigid piston to thrust or push its load upwards.

When the winch handle shown in Fig. 1 is revolved, the teeth of the moving roller engage in the perforations of the band, and cause it to rise in the tubes, and, at the same time, the band is unwound from a drum geared to the crank-handle shaft by a chain and sprocket

Digitized by Google

arrangement. The band carries the smallest tube with it, and, when fully extended a collar on the latter engages internally with the top collar of the next section causing this section to rise also. As the latter commences to rise, the forked lever engages with the pin of the fixed bracket as shown. This has the effect of turning the lever down and clamping these two sections together, so that the mast when fully extended is practically rigid. At the base of the tubes a retaining device is fitted which automatically releases each tube in its turn. The extension of a portable mast is very rapidly carried out, for instance, a 100 ft. mast can be raised to its full height in 60 seconds.

Figs. 2 and 3 show a 150 ft. mast recently supplied to the order of the Japanese Government. These light masts readily lend themselves to mounting on field carriages, in which case the collapsed mast lies horizontal when in motion, and is adapted to be swung into vertical plane on trunnions when required for service.

In addition to light portable masts, the Comet principle has been successfully applied to various descriptions of hoisting apparatus capable of dealing with considerable loads. Fig. 4 illustrates a Comet building mast, which will carry a load of 5 tons, and measures 65 ft. when extended. Rectangular lattice masts are in course of construction for loads up to 12 tons. These loads considerably exceed those to which an ordinary wireless mast is likely to be subjected on permanent service, and telescopic lattice masts of rectangular section may be readily constructed for such stations. In this case the advantages are that, owing to the small compass into which the mast collapses, it is easily transported and shipped, and can be raised into a vertical position and extended without employing the customary costly and complicated gear, so that the erection comes well within the province of the ordinary installing engineer, and, in the case of a foreign contract, it is no longer necessary to ship and transport lengthy and heavy spars, or to pay the expenses of a riggers' staff to deal with them at their destination.

Although it is easy to obtain light topmast spars of suitable length on the spot, it frequently happens that a heavy wooden lower-mast is not procurable, and this has often to be transported from a considerable distance.

In the case of permanent masts the adjacent tubes or lattice sections are clamped together by hand as each is fully extended. The mast may be galvanised or painted, and arrangements are provided for withdrawing the band and detaching the winch mechanism for protection or for use with another mast if required.

Light portable masts, suitable for military, temporary or experimental wireless work, are supplied for heights varying from 40 ft. to 240 ft., and we understand that the Comet masts have been supplied to and adopted by the British and foreign Governments and by the principal wireless telegraph Companies. In addition to masts pure and simple, the Comet Telescopic Mast Co. manufacture a large number of hoisting and elevating appliances of a portable nature, such as masts carrying a platform for artillery observation or searchlight work, portable towers for overhead tramway constructional and maintenance work, hoists and derricks.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" commence in April and October.

(This charge includes all Supplements.)

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s; Europe, 2s; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the 1911 Edition sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription, 5s., post free.

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Now Ready.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d. *Now Ready.*

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett. Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms only, bound strong cloth. Price 5s. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gelpel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d. [Price 10s. 6d. nett.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton. M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully Illustrated. Prize 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free. [Price 3s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. A COMPLETE TREATISE. *Ready shortly.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Hoëner, by Justus Eck. *In Preparation.*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1878).

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

SPECIAL NOTICE.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.: post free, 2s. 3d.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

The report presented at the Annual General Meeting of the Institution last week shows evidence of increasing activity, although the roll of membership does not indicate quite that rapid growth we should like to see. The number of members added year by year is steady but somewhat small. Perhaps this is to be expected under the present conditions of the industry, and in any case it would not be reasonable to expect the growth that was evident a few years ago to be maintained through all time. The commodious premises forming the home of the Institution should now provide some additional attraction. Possibly this is the reason why the membership has grown rather more this session than last, and we hope that the influence of this new asset will be still more apparent in the forthcoming session. By no means the least valuable of the privileges attaching to membership of the Institution is the use of the Library. Hitherto, however, the number of members who have availed themselves of this facility has been small. The fact that the Library is not open in the evenings, except when a meeting is being held, has doubtless somewhat restricted its utility; we are therefore pleased to see that the Council have under consideration opening the Library in the evenings. A further proposa

Digitized by Google

under consideration, which will particularly appeal to provincial members, is the formation of a Lending Library.

With regard to the Papers that were read, these form a fairly formidable list, though we doubt if the average standard of these Papers was quite so high as that reached on former occasions. We notice that the number of regular premiums to be awarded in future to authors has been extended, and we think this is a move in the right direction. So long as the Institution can afford it, the premiums given should be substantial.

One of the most important announcements is that the Council have appointed a committee, consisting of representatives of the Institution and representatives nominated by the Council of the Institution of Gas Engineers, the Institution of Municipal and County Engineers and the Illuminating Engineering Society, to prepare a specification of street lighting to be issued jointly under the auspices of these bodies. The subject is one of very great importance at the present time and anything that can be done to clear up the present unsatisfactory state of affairs will be welcome. The Society first to move in this matter was the Illuminating Engineering Society, but we gather that this movement has been dropped in favour of the Committee appointed by the Institution of Electrical Engineers. We are very glad to see that the Council has taken action in this matter, for it is one that should essentially be handled by the Institution as one of the senior Societies.

There are those who feel that there are already too many meetings of Societies in London and that there is great difficulty in finding sufficient time to attend them. Nevertheless it may be quite desirable to hold informal meetings such as those which the Council now propose in addition to the ordinary general meetings. There is a feeling that the Institution in London lacks that element of sociability so characteristic of local sections. This defect should be remedied to some extent by the proposed informal meetings, the more so as there are many people who do not care to take part in a formal discussion where the remarks are to be reported, but who are willing to speak at an informal gathering. Another suggestion is to hold summer meetings in the districts of the local sections, each meeting lasting three or four days. With these innovations we think it will be admitted that most tastes should be satisfied. Perhaps we may express the hope that the new Council will not throw too much stress upon Mr. ROWELL.

The report shows that the Council have at length pledged themselves to examinations for admission to the class of associate member, and this policy is to come into force after January 1, 1913. Very little information is at present available, but it appears that in addition to an examination in general knowledge, it will be necessary for the candidate to pass in one of four special subjects. It is, of course, impossible to say whether this course will be satisfactory without the fullest details. We are glad to see, however, that due consideration is to be given to the practical side of electrical engineering and that the candidate's admission or rejection will not depend solely upon his answers to the papers. This, we think, is most important, because what we desire is to determine whether the candidate is likely to succeed as a practical engineer, with a proper grounding in theory, rather than an expert theoretically, but possibly useless in practical work.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

General Foundry Practice. By WILLIAM ROXBURGH. (London: Constable & Co.) Pp. xii. + 296. 10s. 6d. net.

The author, after having spent over 30 years in the foundry, and having passed through all the stages from moulder to foundry manager, proposes to put the results of this experience at the disposal of his fellow foundry men, and to help them out of their difficulties. The major part of the book consists of a description of the best ways to prepare moulds, ventilating ducts, pouring gates, &c., for different castings, and explains the most usual troubles to be expected, as well as the best way to obviate them. The number of examples selected is not quite representative, but no doubt the author's experience was the determining factor in the selection. This part of the book will be read with interest, as it is a report of practical experiments, and throws a light on many points of importance to engineers in general.

The author's attempt to generalise, however, and produce a text-book for draughtsmen and students does not appear to have succeeded. In the first place, it is not systematic, all subjects being treated in separate chapters without logical sequence. Thus, moulding and burning of faulty castings are dealt with before anything is said of shrinkage and pattern making. The laying out of a foundry with the conditions for running it on economical lines is explained in the first chapter, whereas one would naturally expect it to form the conclusion of the book. On the other hand, the tables of the analysis of iron of different makes, its qualities and influence on the results obtained, are given in one of the last pages. Again, plain physical explanations of many phenomena would be far simpler than the complicated experimental explanations given by the author, *e.g.*, the remarks on "blistering" or "scabbing" of castings. The treatment of several items is also very far from exhaustive, especially the most important question of mixing iron to obtain castings to a given specification. No attempt is made to solve this problem, the author merely stating that chemists are employed in large foundries for this purpose.

The chapters on such important subjects as the production of malleable iron and brass are kept so very short that the treatment of the respective matter is necessarily incomplete, and therefore hardly useful for practical purposes.

Finally, I should like to mention that, whilst a practical man may introduce a certain number of trade expressions, and may not be expected always to use a terse literary style, it should be a matter for the publishers to have the proofs read with a view to smoothing off the phrases which strike one most disagreeably throughout this book, and, where necessary, to correct expressions like "a good going cupola," and others which openly defy grammar.

R. ORSETTICH.

Imperial Telegraphic Communication. By CHARLES BRIGHT, F.R.S.E., M.Inst.C.E., M.I.E.E. (London: P. S. King & Son. 3s. 6d. nett.

Mr. Bright is a persistent writer on matters relating to telegraphic communication and he has taken the opportunity offered by the meeting of the Imperial Conference now sitting in London to prepare in handy book form a collection of the Papers he has read and articles he has contributed to various societies and to the reviews. Included in the list is the Paper recently read before the Royal Colonial Institute. However one may differ from Mr. Bright as to the practical utility of some of the suggestions he has put forward from time to time, there is no denying that he has given much attention to this important question, and it is only right that due credit should be given to him on this account. He has done the spade work. We think Mr. Bright is wrong in coming to the conclusion that the public discussion of cable rates has led to the reduction in rates of which he takes account. We feel little doubt that the majority of these reductions have been brought about, in the first place, by negotiations ranging over

Digitized by Google

long periods between the cable companies and the different Governments, and more especially as the result of understandings and agreements between the respective parties as influenced by the volume of traffic, as in the case of the rates for Indian traffic. Presumably in this matter Mr. Bright is only one of the public, and so is unacquainted with the constant flow of negotiations going on in connection with these matters. Besides being timely, Mr. Bright's book is an instructive contribution to a subject in which the public are becoming interested and every day better informed. It is largely concerned with the history of telegraphic communication and records many of the principal events that have led up to the development of the great system of submarine telegraphy which now encircles the earth and makes speedy communication possible with all countries.

Engineers' Pocket Dictionary: English-German-Dutch. By W. H. Steenbeek. (London: Whittaker & Co.) Pp. 158. 2s. net.

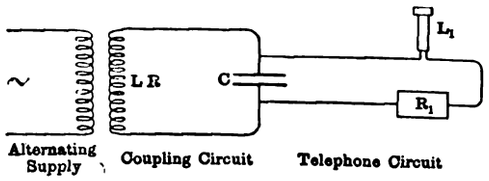
This book is intended by the author for the use of engineers who belong to either the English, Dutch or German nations on occasions when they are working in one of the two countries other than their own. An English engineer, supervising the erection of plant in Holland, and ignorant of Dutch, will, it is hoped, turn to this book with a sigh of relief and find there the phrase which he desires laid down in the language of the country. The theory is excellent, but we are not so sure about the practice. The way for those who depend upon books of this class for conveying their thoughts in a foreign language is hard. For one thing idiom seems there to find no place, though idiom is the principal feature of all conversation. Again, in this particular book, the translation is not always well done. For instance, "Freilauf" is not a correct rendering of the phrase "air-gap" when used in an electrical sense, nor is it explained that "Morgen" may sometimes mean "to-morrow" as well as "morning." This may lead to confusion in Germany. We recommend the learner to use this book with caution. It should, nevertheless, prove useful as a refresher to the engineer who is already well acquainted with Dutch or German. Its small size makes it convenient for carrying in the pocket.

A METHOD FOR THE DETECTION OF HARMONICS IN AN ALTERNATING CURRENT, AND FOR THE MEASUREMENT OF INDUCTANCES.

BY H. SMITH, B.SC.

Summary.—The author determines the harmonics in an alternating current by coupling to the circuit under test (by means of a transformer) a circuit including inductance and capacity, these being varied until the natural frequency of the circuit is the same as that of any desired harmonic. The harmonic is detected by a telephone across the capacity. Inductances are measured by substitution in a tuned circuit, the inductance being readjusted to give the note again after inserting the unknown inductance.

In alternating-current work the distortion of the current wave due to resonance between harmonics and some part of the circuit is a frequent and well known occurrence, but I do not remember the principle of resonance being utilised for the



examination of the harmonics present in an alternating supply. The method described below appears to offer a very sensitive and, at the same time, very simple test for the presence of harmonics up to a very high order.

If we have a circuit consisting of an inductance L and a capacity C, we can produce an oscillating circuit of low frequency, which can be coupled with the alternating supply which is to be examined. By altering the value of C we can give to the circuit the same period as any of the harmonics. To test when the circuit is in resonance with any particular harmonic, a telephone is joined across the condenser, and a note is heard which has the same pitch as the frequency of the circuit. It is necessary that a fairly large resistance (10,000 ohms or more) should be placed in series with the telephone. As C is varied from zero upwards, all the harmonics are heard in turn in the telephone, each harmonic producing a note which rises to a maximum with a certain value of the capacity. To find what harmonic has been reinforced by resonance, all that is necessary is to find the pitch of the note with a sonometer and divide by the frequency of the fundamental; or if L and C are known, the frequency of the circuit divided by the frequency of the fundamental will give the harmonic. Also, since the pitch of the note is the frequency of the circuit, if C is known and L unknown, the value of L may be calculated from the formula $n=\frac{1}{2\pi\sqrt{LC}}$, where n is the pitch of the note. As C is varied till a particular note in the telephone reaches a maximum intensity, the current through the telephone due to any particular harmonic must also be a maximum.

Let L and R be the inductance and resistance of the coupling circuit, L_1 and R_1 be the inductance and resistance of the telephone circuit. Then it can be shown that the current through the telephone is given by

$$i=\frac{E}{\sqrt{C^2\omega^2x_1^2x^2-2\omega^2C(L_1x^2+Lr_1^2)+X^2}}$$

where $x_1^2=R_1^2+\omega^2L_1^2$,
$x^2=R^2+\omega^2L^2$,
$X^2=(R+R_1)^2+\omega^2(L+L_1)^2$ and $\omega=2\pi n$, where n is the frequency of the harmonic,
E = E.M.F. produced by the change of the lines of force through the coils of the coupling circuit.

This is a maximum (the capacity being varied) when the denominator is a minimum, *i.e.*, $\frac{d(\text{denominator})}{dC}=0$, This gives

$$2C\omega^2x_1^2x^2=2\omega^2(L_1x^2+Lr_1^2)$$
$$\therefore C=\frac{L_1x^2+Lr_1^2}{x_1^2x^2}$$
$$=\frac{L}{x^2}+\frac{L_1}{x_1^2}=\frac{L}{R^2+\omega^2L^2}+\frac{L_1}{R_1^2+\omega^2L_1^2}.$$

The inductances of the telephone used varied from 4 millihenries to over 100. R_1 was made to be over 10,000 ohms, so that the value of the second term was quite negligible compared with the first. As the resistance of the coupling coil (never more than 15 ohms) was negligible, compared with ωL, the value of C necessary to produce a maximum current in the telephone for any particular harmonic is given by

$$C=\frac{1}{\omega^2L},$$

but $\omega=2\pi n$, where n = frequency of harmonic,

$$\therefore n^2=\frac{1}{(2\pi)^2LC}$$
$$\therefore n=\frac{1}{2\pi\sqrt{LC}}.$$

Therefore the condition that the current through the telephone should be a maximum for a particular harmonic—the resistance of the telephone circuit being very large—is that the coupling circuit should be in tune with the harmonic. If the telephone has a very small resistance and a fair inductance then C is given by $n=\frac{1}{2\pi\sqrt{\frac{L_1+LC}{L_1L}}}$ and good notes are heard. Generally, however, the resistance of the telephone amounts to about 100 ohms. It therefore produces the best notes when a large resistance is put in to prevent it affecting the oscillations of the main circuit.

Observations.—In the results given in Table I., C is the capacity in microfarads necessary to produce a certain note in the telephone at its maximum intensity, P_1 is the frequency of the coupling circuit under these conditions and P_2 the pitch of the note. Needless to say, to produce perfect agreement betwe

Digitized by Google

the numbers, the tuning of the coupling circuit must be fairly sharp (this is so if the resistance of the circuit is kept low) and the ear of the operator sensitive to pitch.

L=0·157 henry, resistance of telephone circuit=10,000 ohms to 100,000 ohms.

R=15 ohms.

Period of alternating current=about $\frac{1}{80}$ sec.

Table I.

It was found that the capacity necessary to produce a maximum intensity for a given note varied from time to time. The pitch of the note varied in the same way. Even while listening the pitch of a note would sometimes flatten or sharpen a little, due no doubt to the alteration in speed of the machines producing the current.

Table II. shows how the capacity varied from time to time.

Table II.

The 13th harmonic produced only a faint note and was sometimes slipped over altogether.

The resistance used in the telephone circuit was a variable one, from 10,000 to 100,000 ohms. Sufficient resistance was put in to bring out the character of the note, but not too much to make it inaudible by reducing the current.

To test for higher harmonics a smaller inductance was used so as to be able to use large capacities. Unfortunately I was not able to measure this inductance except by the principle explained in this Paper.

Here the pitch of the note is taken as the frequency of the coupling circuit, and from this the value of the inductance was calculated in millihenries. All the harmonics produced very fine notes until the 15th was reached, when a much louder note was heard.

The results given in Table III. were taken on two different occasions. The disparity for the value of the inductance given in the two cases was probably due to the sonometer not being quite in tune in one or both cases.

The current used was the alternating current supplied to the College by one of the Newcastle companies. Two machines of practically identical structure are used on the College circuit; both are turbo driven, revolving armature dynamos.

Measurement of Inductances.—For measuring inductances smaller than a millihenry a method of substitution must be employed. If the coupling circuit consists of a known inductance and capacity (L and C) which is tuned to a certain harmonic, and the inductance (L_1) to be measured be then placed in the coupling circuit, a new value of the capacity (C_1) will be needed to tune to the same harmonic. We therefore have $L_1 = L(C - C_1)$, from which we can calculate L_1. Provided the standard inductance with which we are comparing is known accurately, this is a fairly satisfactory and a very quick method for measuring an inductance less (but not much less) than 1 millihenry. Inductances larger than 2 millihenries can be measured directly as explained in a previous part of the Paper. Inductance as large as 157 millihenries I have been able to measure very easily, and probably much larger inductances than this can be measured by this method. Everything depends, however, on the resistance of the inductance not being too large.

THE HEATING OF CABLES WITH CURRENT.

We give below an account of the discussion that took place at the meeting of the Institution of Electrical Engineers last week, when Messrs. S. W. Melsom and H. C. Booth read their Paper on this subject. An abstract of this Paper appeared in our last issue.

Mr. C. P. Sparks drew attention to the exceptional nature of the Paper. It had been written and brought before them at the request of a Committee of the Institution, and it described the outcome of an investigation that had lasted over two years. The Wiring Rules Committee had on several occasions considered the question of investigating the permissible current-density in conductors, but the difficulty arose due to the time and expense involved, and it was not until the Committee got the help of the National Physical Laboratory that it was possible to investigate the matter thoroughly. The Committee considered that the industry owed a debt of gratitude to the Laboratory and to Dr. Glazebrook. Further, they had been greatly assisted by the cable makers in supplying the necessary materials. In the past the governing factor as to size of conductors was the pressure drop, the heating hardly coming into the question at all. The new Rules recently issued by the Institution were based upon the permissible temperature rise, a more reasonable basis. Attention had been drawn in some quarters to the fact that the Wiring Rules permitted what at first sight appeared to be an exceedingly high current-density in small conductors; but it was not pointed out that the Rules at the same time lowered the permissible current-density for large rubber cables. A study of the Paper would show that they were working on a very conservative basis. It had also been suggested that it was the wiring contractor who had brought about the alteration to his benefit; as a matter of fact, contractors had nothing to do with it. The real reason for the investigation was the largely increased use of electricity for power work. The engineers of the electricity supply undertakings were fully alive to this, and were the people responsible for bringing about the alteration. The leading insurance companies, the supply companies and the municipalities had adopted the rules after these had been submitted to them. There could not be such a consensus of opinion in favour of the Rules unless they were drawn on a practical basis. The Committee hoped that they would be able to go even further in the future, and investigate the question as to what was the critical temperature rise. The deterioration of rubber and paper over long periods would, he hoped, be investigated, and it might be found that it was possible to go beyond the present current limits. In conclusion, he thought the Paper would remain as a standard work.

Mr. H. Human said the subject was one in which he took considerable interest. In 1884, when getting out a set of rules for his Company, he realised that to limit the current per conductor on a basis of a certain number of amperes per square inch was a fallacy, and that the only rational way was by a temperature limit. He therefore got out a table allowing a rise of temperature due to current of 10° C., based upon the work of Prof. G. Forbes. In 1891 he found it necessary to re-cast it upon the later data of Dr. Kennelly, who tackled the subject afresh from the point of view of rubber-covered conductors in casing. But when in 1897 the Institution revised their Rules and issued a current-density table upon a basis of 10° F. rise of temperature, he scrapped his own table for the sake of uniformity. It now turned out that that table was founded upon insufficient data. Fortunately the smaller sized conductors carried an ample margin of safety, and even most of the larger sizes were well within the present limit of rise of temperature, so no harm had been done. The new Table carried the hallmark of the National Physical Laboratory, and in his opinion would live as long as they were committed to rubber and copper.

Mr. J. F. C. Snell said that, although they now found that small cables had been much under-rated and some of the larger sections had been over-rated under the old Wiring Rules, they could console themselves with the thought that no evil results had happened. The new issue of the Rules rated cables in the correct way—viz., on the temperature rise of the conductor. He hoped that further investigations would be made on the lines of Fig. 17 of the Paper. It was shown that, where a high current-density was required for a short time each day, lead-covered or armoured cables laid direct in the soil were capable of carrying higher currents than those either laid solid or in ducts. It would be very valuable if the authors could continue their researches and ascertain to what current-density underground cables could be safely used, especially three-core paper-covered cables. He noticed that the authors did not deal specifically with the effect of current-density and temperature rise upon the dielectrics used; this would be interesting information, and form a useful extension of the treatise at present before them.

Mr. W. R. Rawlings said that the Paper was a text book and was really beyond criticism. He had seen some of the tests carried out, and could testify to the care taken. He thought the new rules had done more for the wiring contractor than for the supply station engineer. They would sell fewer large cables, but 10 times the number of small wires. Where it would cost under the old rules £100 to lay down a small heating installation it could now be done for £30. A large number of heating installations had simply been barred by the enormous cost of carrying them out under the old rules. He thought the Paper, in conjunction with the Wiring Rules, would do more to bring about the desirable day load for central stations than anything hitherto brought forward.

Digitized by Google

Prof. A. W. PORTER said the authors had the kindness to refer to a small experiment of his shown at the Royal Society soirée on the anomalous affect of lagging thin wires. That was not the first time the experiment had been shown by him. He showed the identical experiment eight years ago, and it had been seen since by a number of engineers. He was rather surprised that it was not apparently known to the members of the Wiring Committee. The first time it was shown at a scientific society was about two years ago (Nov. 13, 1908) in a Paper read before the Physical Society. The present Paper was one of very great interest. There were, no doubt, a number of things in the Paper which he could not have predicted accurately from the experiments he had made up to date; but, in the rough, one might have years ago predicted approximately the results which the authors had obtained. They could not, however, rely upon theoretical conclusions, and they must have experimental verification of what might have been predicted. The authors were to be congratulated upon being the first to obtain experimental evidence of the necessary thoroughness and precision.

Mr. A. WHALLEY asked whether the outer lead of the concentric cables was insulated, and also whether the results obtained with lead-covered rubber cables were identical with those for lead-covered paper cables. Lead-covered rubber cables were used extensively in ship installations, and information on the current density permissible in such cables would be valuable.

Mr. C. C. PATERSON pointed out that, from the point of view of voltage drop, although on the smaller sizes of wire the new rules increased the permissible current-density from 1,500 to 3,000 amperes per square inch, lighting installations using tungsten filament lamps would not be worse off than those that were designed under the old rules for carbon filament lamps. On account of the temperature coefficient of tungsten lamps, a 2 volt drop on the line with tungsten lamps caused about the same change of candle-power as a 1 volt drop with carbon lamps, and so nearly twice the current-density was possible. This appeared to him one of the chief justifications for the adoption of the new rules for lighting installations.

Mr. T. E. RITCHIE said that in practice it had been considered an advantage to have the grooves in wood casing no larger than necessary. This opinion the authors had demonstrated to be correct. With reference to the increase in the rating of the smaller cables, he could assure them that the effect of this alteration on the motor industry would be immediate and pronounced. Attention had not been called to the importance the alteration would also have on arc lamp wiring; in that a certain drop in pressure had to be provided, so there would be no difficulty in running up to the full limits of the new curve. That was so interesting a point that he had worked out the cost on the new basis for a large arc lamp installation at a locomotive works, where the wiring amounted to a very considerable sum. He found that the saving in capital outlay represented no less than 17 per cent. He also asked the authors whether they had considered the question of pit-shaft cables, which would differ materially from any of those referred to in Fig. 17. In pit shafts there was dampness and very unusual conditions in the way of forced draught.

Dr. R. T. GLAZEBROOK, who was in the chair, said it was very gratifying to him to listen to the remarks that had been made in regard to the work of the Laboratory. The way the Laboratory had been assisted was an instance of how when manufacturers realised that an investigation was really helpful to their industry they were ready to come forward in a practical manner. The work connected with the issue of the new Wiring Rules had been no light task, and they were much indebted to Mr. Sparks and other members of the Committee for their efforts to bring the rules to their present condition. Suggestions had been made for still further work in the same direction, and if the work could proceed they would be glad to do it at the Laboratory.

Mr. C. BEAVER (communicated) said he had always been surprised that while the tables dealt with single cables up to 1 *square* inch, they ignored twin, concentric and multicore cables, in which the maximum current densities would be decidedly lower for a given temperature rise. He pointed out that it was not so easy as the authors inferred to conduct heating tests on cables as laid *in situ*. The authors did not state what the original temperature was in their experiments. To a considerable extent this factor determined the temperature rise. Again, one or two of their observations did not hold for buried cables, namely, that there was little difference between rubber and paper-insulated cables laid under similar conditions: also as to there being only a small difference between rubber cable in casing and in iron tubes in air. For certain ranges of time before a final steady temperature was reached, and particularly when dissipation of heat was chiefly effected by radiation or convection, and not by conduction, the effect of reflection of heat from the interior of a lead sheath was quite marked and appreciably accelerated the rate of heating. This might be of importance to central station engineers in connection with intermittent or peak loads. Many other more or less unexpected results limited the application of the authors' conclusions.

Dr. A. RUSSELL (communicated) thought the authors' theory on the cooling of cables might be considerably improved by taking into account the important results recently obtained by the French physicist, Boussinesq. (In his communication Dr. Russell indicates therefore a more rigorous method of proof and gives a historical résumé of the problem.)

Mr. S. W. MELSOM, in reply, said, with regard to the effect of temperature on the insulation resistance of the cables, Mr. Snell mentioned that the decrease would be about 4 per cent. per degree Centigrade, whereas, according to observations made by the authors, the decrease in the insulation resistance of a paper-insulated cable was more nearly 50 per cent. for a rise of temperature of 1°C. He had not intended to intimate that Prof. Porter had recently shown the experiment for the first time at the Royal Society, but only that he had there seen it for the first time. Prof. Forbes had suggested in 1884 that the results would be as shown. With regard to Mr. Whalley's remarks, the outer as well as the inner leads of the paper-insulated lead-covered concentric cables were insulated. The authors had not made any experiments with lead-covered rubber-insulated cables, but the temperature rise in such cables could be readily calculated. It was obvious that they would not get any hotter than rubber cables without the lead sheath. Dr. Kenelly's formula was, of course, simple; but it was not strictly accurate for covered cables, as it did not take into account the variations brought about by the varying outer diameter of the covering. With regard to Mr. Ritchie's remarks, curve No. 4, Fig. 17, showing tests of a cable when placed in an air shaft, was the nearest approximation they had been able to get in the laboratory to a colliery shaft.

CORRESPONDENCE.

THE ORIGIN OF "ATMOSPHERICS" IN WIRELESS TELEGRAPHY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the correspondence under the above heading in your last issue, I should like to point out that I proposed the use of directive aerials for the investigation of the origin of "atmospherics" some time before any of the experiments mentioned.

The following is an abstract from a Paper ("Proceedings" of the Royal Society, A, Vol. LXXVII., 1906) which I presented to the Royal Society on March 15, 1906, on the subject of directive aerials:—

"When using horizontal receiving wires arranged as described in this Note, I have often noticed that the natural electrical perturbations of the atmosphere or stray electric waves, which are generally prevalent during the summer, appear to proceed from certain definite directions which vary from time to time. Thus, on certain days, the receiving instruments when connected to wires which are oriented in such a way as to possess a maximum receptivity for electric waves coming from the south will give strong indications of the presence of these natural electric waves, whilst on differently oriented wires the effects are at the same time weaker or imperceptible. On other days these natural electric waves may apparently come from other directions.

"It would be exceedingly interesting to investigate whether there exists any relation between the direction of origin of these waves and the known bearing or direction of distant terrestrial or celestial storms from whence these stray electric waves most probably originate. A considerable number of observations would be necessary to determine whether there exists any relation between the bearing of storm centres and the direction of origin of these natural electric waves. I propose to carry out some further investigations on the subject."—I am, &c.,

Adelphi, W.C., May 30. G. MARCONI.

NATIONAL TELEPHONE COMPANY'S STAFF DINNER.

IMPORTANT STATEMENTS BY THE POSTMASTER-GENERAL.

The 17th annual dinner of the National Telephone Co.'s staff was held at the Hotel Cecil, London, on Thursday evening last. Mr. ALBERT ANNS again occupying the chair. The company supporting Mr. Anns included the Rt. Hon. H. L. Samuel, M.P. (H.M. Postmaster-General), Mr. Geo. Franklin (President of the National Co.), Mr. S. H. Sands (vice-president), Lord Harris (director), Sir Robert Hunter (G.P.O.), Sir John Gavey, Mr. W. A. Smith (director), Mr. C. S. Agnew (director), Mr. G. H. Robertson (director), Mr. Alexander Siemens (President of the Inst. of Civil Engineers), Mr. S. Z. de Ferranti (President of the Inst. of Electrical Engineers), Major W. A. J. O'Meara (G.P.O.), Mr. Stanley J. Goddard (general superintendent of the Company), Mr. Frank Gill (chief engineer of the Company), Mr. W. Duddell, F.R.S., Mr. G. F. Preston (G.P.O.), Mr. W. E. Hart, Mr. A. Ross, Mr. G. Sutton, Mr. W. Aitken, Mr. J. C. Chambers, Mr. R. B. Claxton, Mr. C. B. Clay, Mr. A. E. Cotterell, Mr. H. M. Darville, Mr. J. E. Kingsbury, Mr. P. P. Kipping, Mr. F. A. B. Lord, Mr. G. Morgan, Mr. C. F. Moorhouse, Mr. C. J. Phillips, Mr. T. Fletcher, Mr. E. J. Hidden, Mr. B. S. Cohen, Mr. C. W. Salmon, Mr. F. E. Sims, Mr. H. T. Waddy, Dr. R. M. Walmsley, Mr. F. D. Watson, &c.

After the loyal toasts, the CHAIRMAN gave the toast "The National Telephone Company," and said: Gentlemen, this is a memorable occasion, not only because it must of necessity be the last of these annual

Digitized by Google

gatherings, but because it is our good fortune to have with us to-night, for the first time in our history, His Majesty's Postmaster-General. I need not say how warmly we welcome him, or how much we appreciate his presence and that of the other representatives of the Post Office. The British Post Office we know stands pre-eminent among the nations of the world in connection with the collection and delivery of letters. When we talk of the Post Office in telephone circles we naturally think of the Parliamentary chiefs who have presided over the destinies of that Department during the period of the existence of the National Company; and when we remember that the position of Postmaster-General has been filled, as it is at the present time, by able and distinguished men, and when behind the Government there is Sir Robert Hunter, you will appreciate how strenuously the directors have had to fight, in cricket parlance, to keep their end of the wicket up; and it is not improbable that on January 1, 1912, we may still be "not out" (laughter and cheers). Last year we lamented the loss of many loyal servants of the Company, through no fault of their own, but because they were forced to leave the Company's service to seek employment elsewhere. It was a great relief to all of us, and one we received with much thankfulness, when the President, with the hearty concurrence of every member of the board, declared that, no matter at what cost, these dismissals should cease, and our reward has been the increasing prosperity of the Company. There was another matter about which we were very unhappy last year—as to your future as servants of the Crown. I was hoping, and I had good ground for hoping, that the President to-night would have been able to indicate to you that a satisfactory arrangement had been made regarding your future as servants of the State; but this confirmation of my hopes is not yet. After your splendid services for the State—for they have been rendered to the State, of which you have been licensees and have contributed largely to the national revenue—and having regard also to the recommendation of the Select Committee of 1905 that no servant of the Company should suffer in the transfer, I feel that it is not right and is not just that you should continue to suffer this cruel anxiety with regard to your future prospects as servants of the Crown. My contention is, and I submit it very respectfully, that if the rules and regulations of the Civil Service do not adapt themselves to the present condition of affairs, then these rules and regulations should be amended, so that justice (and you are asking for nothing but justice) should be granted to every member of the staff (hear, hear). I know this is a matter upon which you feel very keenly, and I cannot trust myself to say anything more, except to reiterate my firm conviction, which I have expressed on several previous occasions, that in the end you will all receive fair treatment. Since the last dinner you have started on the colossal task of making an inventory of the multitudinous items which are called our plant. There has been recently a census of the people, and this has been a great task, but in regard to details it will not compare with the work which you have in hand. In the census papers we were asked to state our ages, but we were not asked to state what our expectation of life was, what our unexhausted capacity was, or on what basis we were making provision for the depreciation taking place in us day by day (laughter). Taking all the facts into consideration, it is not to be wondered at that a doubt has arisen in many men's minds as to the necessity for this colossal work in order to determine what is the value of our undertaking; but Parliament has so declared it, and all we have to do is loyally to carry out the terms of the agreement of 1905.

I will now give you a few figures to show the extent and magnitude of the Company's business. On December 31, 1910, we had 1,570 exchanges open, over 530,000 stations, and £16,000,000 had been expended on capital account. I want to say in regard to the last item that, in view of the uncertainties of 1911, the directors' policy has always been to charge the capital account as lightly as possible, and to let the heavier burden fall on revenue. I mean that had we been a continuing company, such as, for instance, a railway company, the capital account would have been swollen, very properly, to a considerable extent. What I wish you to understand from this is that the capital account does not represent the full amount you have spent on this business, in the same way as revenue account does not disclose the true profits derived from this undertaking. Our gross revenue is over £3,400,000, and, as you know, the first charge on this revenue is the Government tax, which was last year about £230,000, and will before the end of the licence mount to a total of 3¾ millions of money—that is to say, you have made the nation a present in the shape of royalties of an amount nearly equal to the value of two "Dreadnoughts." On the top of these royalties you have rates and taxes of about £150,000, and this taxation is without representation! Despite this burden, however, you have shown a net profit of over £1,100,000—a great achievement.

With regard to the staff, of which I am proud to be a member, and which represents about 18,000 men and women, I must use the words of the President at the recent meeting of shareholders, "that the staff, for efficiency and loyalty, was second to none of any of the companies with which he was associated or had any knowledge." I am thankful that, so far as the staff is concerned, there is no question of its necessity or its suitability to conduct the business which you have hitherto carried on so successfully. Now, what is to be paid for this great business and for this organisation? Well, you are not to be paid for the business and you are not to be paid for the organisation. The proposal is that you should be paid only for a portion of your plant, land and buildings, and that at a depreciated value. Taking these facts into consideration, I think you will agree with me in my remarks of last year, that it will be a transaction without parallel in the commercial history of the world. In these circumstances I cannot and will not believe that the Government will approach a settlement, either as regards the staff or as regards the shareholders, in a niggardly spirit. When Benjamin Disraeli, with the foresight so noticeable in members of the gifted race of which he was a brilliant example, acquired the Khedive shares of the Suez Canal Company, the advantage to the country was very great; but I consider that that will be as nothing compared with the advantage that will come to the nation from the social, domestic and commercial point of view, from this telephone business, if it passes into the hands of the State or to some Authority that has a free hand, a thing which we never had; unlimited capital, which we never had; and statutory powers to enable it to do the work in the quickest and most economical manner, which, again, we never had. I do not mean that we have not done well; on the contrary, you have every reason to be proud of the magnificent business you have created and established in despite of the almost unsurmountable obstacles and difficulties that have been placed in your way by Government, by local authorities, and by individuals. When the true history of the National Telephone Company comes to be written, I feel confident the verdict of posterity will be that we deserved well of the nation (cheers). It may be that, to some of us, the next few months will bring the parting of the ways, and we may have to say good-bye to the loyal comrades with whom we have worked in kindly fellowship for so many years. For some of us it may mean making a new start in life, perhaps in the New World, where energy so often meets with its due reward; but when the end comes I confidently anticipate that the President, voicing the sentiment and feelings of the board of directors, will send to each and every one of you the message, "Well done, thou good and faithful servant." Now for the last time I have to ask you to wish the National Telephone Company during the few remaining months of its existence a continuance of that bright prosperity that is at present shining upon it, and with the toast I couple the name of one who has been a just chief and true friend to every one of us, our President, Mr. Franklin (loud cheers).

Mr. Geo. Franklin, who was accorded a hearty reception, in reply, said: It is with a feeling of real pleasure I respond to the toast of the "National Telephone Company" on the occasion of this, our last annual dinner. I would remark that if this is a funeral feast, and if the meats of which we have partaken are the baked meats which accompany such an occasion, we have no reason to be downhearted. I am able to assure the Postmater-General to-night, as I have assured his predecessors, that among all the valuable assets which will be taken over with the property of the National Telephone Co. none are of greater value than the able and devoted staff of the Company. I am speaking for all my colleagues in bearing testimony to the feeling which the board of directors have with regard to the satff. Mr. Anns has reminded us that 31 years ago, or thereabouts, the National Telephone Co. was born of the Post Office, and I may say that the Post Office stands in the position of parent of the Company. We read that man was born unto trouble. Certainly the National Telephone Co. has been born unto a succession of troubles. Year after year since it came into existence the Company has been the object of a series of attacks, and perhaps we must recognise in this a form of parental discipline or concealed parental affection. Parents, we learn, often find their children a source of expense; but in this case it is the child which has found the parent a great source of expense. No less than 23 per cent. of the Company's net earnings, or 10 per cent. of its gross earnings, have been absorbed by its parent, and this has been exacted for the full term of 31 years or thereabouts, and for no consideration at all. Possibly on the demise of the offspring, which is to take place shortly, the latent affection of the parent, which has so far been concealed from our eyes, will be revealed and become more manifest, in which case many of the difficulties which appear to confront the lawyers and surveyors will be things of the past. There are certain solid facts which remain to us, and one of these is that the number of messages transmitted during the past year over the Company's system number something like 1,500,000,000, and this, I think, is a record of which any company can be proud. Mr. Anns has also referred to the gross income of the Company, some 3½ millions, and to the number of our stations, about 550,000. These figures are eloquent, and show that, notwithstanding the difficulties which have been imposed upon us, we have endeavoured—as Englishmen do as a rule—to grapple with them and turn them to the best possible account. This brings me to the position of the staff, and I would like to take this opportunity of referring to the great additional burden which has been placed upon the staff this year by reason of the inventory now being prepared for the benefit of the Postmaster-General. This will altogether occupy something like 15 months, and a very large staff is engaged upon it. The point I wish to make is that the board of directors are full of appreciation of the staff's ready response to the call made upon them in connection with the taking of this inventory, are full of appreciation of the admirable way in which this inventory has been made so far, and are full of appreciation of the fact that without any hesitation the officers of the Company responded willingly to the heavy call thus made upon them. A no smaller meed of appreciation should be given to those who are stopping at home and doing the work of those who have gone on to the inventory staff. This latter service is only a little less heroic, certainly no less serviceable, and, as I have said, none the less appreciated by the directors. As to the transfer of the staff to the service of the State, I wish to say that the policy and desire of the Board is that no officer of the Company shall be prejudiced by reason of his transfer. This was a recommendation of the Select Committee of 1905, a recommendation which I have no doubt will have full weight with H.M. Postmaster-General, who has given us the pleasure of his company here to-night. Those of us who have seen and watched with keen interest the attitude which the present Postmaster-General has assumed on questions affecting the large staff under his authority may, I think, feel assured that he will not be unmindful of his duty to the staff which he is about to take over from this Company, or of the recommendation, which is just and necessary, that all members

Digitized by Google

of the Company's Pension Fund Staff shall be placed upon the establishment of the Post Office under conditions not less favourable than they are at present enjoying. As to the remainder of the Company's staff, a large number will, I understand, be placed on the establishment of the Post Office, and in all these cases the directors will endeavour to obtain fair and equitable treatment—this not only in the interests of justice, but we belive in the best and truest interests of the Post Office.

One matter of very great interest to the staff is the method of dealing with the pension fund. Without going into legal technicalities, I understand that it is not provided in the pension fund trust that the fund should be closed and wound up on the expiration of the Company's licence. The directors, however, and the trustees of the fund, consider that it is very desirable in the interests of the staff that the funds shall be closed on December 31st next, and the assets distributed as quickly as possible thereafter. The central committee of the Staff Transfer Association have asked that steps shall be taken to have the fund wound up on December 31st. This can only be done by the consent in writing of the majority of the members of the fund, and I am advised that the position of existing pensioners must not be adversely affected. These are the arrangements which are the necessary sequence of the termination of the Company's licence, and, although I am unable to carry the matter further, there is one gentleman among you who may be able to do so; and if we can convince him, as I think we can, that the taking of any other course than that I have indicated with regard to the pension fund staff will bring about an injustice, then I am sure the present Postmaster-General is the very last man to do anything of that nature. Before I conclude I wish to repeat, on behalf of my colleagues, our warm appreciation of the valuable service which has been rendered by the staff in the years which have gone by, and of the admirable manner in which the peculiar difficulties of the position have been met. These difficulties could never have been surmounted but for the vigilance and uprightness of the staff (loud cheers).

Mr. S. J. GODDARD proposed the toast of "Our Guests." He said: We welcome Mr. Samuel to-night, not only in his capacity of one of H.M. Cabinet Ministers, but also as representative of that great department which has always been so intimately connected with the telephone service, and will be more intimately connected with it in future. We welcome him as representing those members of his staff with whom we are, each of us in our several spheres, continually brought into contact day by day. Another of our guests is Mr. Ferranti, President of the Institution of Electrical Engineers. With the names of these two gentlemen I couple this toast. We have also with us Mr. Alexander Siemens, President of the Institution of Civil Engineers, and Mr. Duddell, the inventor of that most extraordinary piece of apparatus the oscillograph. There are very many more of our old friends with us, including Mr. Claxton, who has borne a great share in the heat and burden of the day; also Mr. Preston, who, once with the National Company, is now successfully working with the Post Office. All these guests we honour and welcome.

The Right Hon. HERBERT L. SAMUEL, M.P., H.M. Postmaster-General, in responding, said: Mr. Chariman and Gentlemen, I appreciate, I need hardly say, very greatly the honour which you have conferred upon me in including me in your list of guests at the staff dinner of the National Telephone Company, and I must thank you for the invitation you have extended to me so kindly and for the welcome you have given me with such cordiality. On my own behalf and on behalf of my fellow guests I thank you very warmly. There are, it is true, certain divergencies of interests between the Post Office and the National Telephone Co. which are now in process of more or less amicable settlement. The settlement certainly is being conducted, and I think will be conducted, without any bitterness. The points at issue which remain for decision arising out of the execution of the policy decided upon between the two parties six years ago will be decided, I feel sure, with good feeling on both sides, and the presence at this board to-night of so many of the heads both of the Company and of the Post Office is a happy proof of the good feeling shown on both sides. You gather hereto-night at what you have been told by previous speakers is the last dinner of the National Telephone Co's staff. You will naturally feel some sentiment of regret at the severance of a connection which has lasted for so many years between yourselves and the Company, a well managed Company, which has built up a great business with profit to its shareholders in spite of those onerous exactions on which the President dealt, with advantage to the British public, and with, I trust, advantage to those whom I see around me to-night. This is a domestic gathering, my presence at which, I feel, almost might be regarded as an intrusion (No, no.) You here, I am afraid, may look on the Postmaster-General as a portentous shadow falling across the brightness of this festive gathering (laughter). I do not know whether any of you are acquainted with the beautiful poem of him whom I regard as the greatest of living poets, William Watson. He uses these words:—

Ah! but the apparition (myself in this case) the dumb sign,
The beckoning finger, bidding us forego
The fellowship, the converse, and the wine,
The song, the festal glow.
And ah! to know not, while with friends we sit,
And while the purple joy is passed about,
Whether 'tis ampler day divinelier lit
Or homeless night without.

Well, if I am to be regarded as the apparition, the dumb sign, the beckoning finger, I can assure you there is every probability that you will find, not homeless night, but ampler day divinelier lit when you go over to the other world which the Post Office opens to you (Cheers.) I can assure you that throughout, the interests of the staff of the Company have been fully considered and will be fully considered, and that it is not merely my desire, but my determination, and the determination of the heads of my department, to see that full justice is done to all and to each of the members of the staff of the National Telephone Co. on their transfer to the State (Cheers.) You are aware of the general lines upon which, so far as the staff is concerned, the transfer will be effected, for they were declared to the House of Commons by the then Postmaster-General, Lord Stanley, in a Memorandum read to that House in 1905. I should tell you to-night that it has been thought advisable in certain particulars to modify certain conditions then expressed, but I may relieve your minds by saying that all those modifications are favourable to the members of the staff (Cheers.) Lord Stanley then said that the Postmaster-General, whoever he might be—and, as we all know, Postmasters-General are a fleeting race (laughter) and he foresaw, no doubt with some certainty, that he would not be, when 1911 came, holding the position he then occupied—but he announced, and his pledge is binding upon his successor, that whoever in 1911 should be Postmaster-General would take into the service of the Post Office the members of the National Telephone Co.'s staff who were not clearly disqualified, and who were not in the fortunate position of being in receipt of great salaries, to whom continued employment would of course be a matter of entire indifference (laughter.) But the rest of the staff who had not less than two years' service would, Lord Stanley stated, be taken into the employment of the Post Office. But I have since been able to announce that not only those who have more than two years' service, but the whole of the staff, irrespective of the length of their service, with some very few and exceptional cases, would be taken into the service of the Post Office; and we are looking forward to having the advantage and assistance of those highly trained and highly efficient body of men, many of whom will be taken into our employment, if they so desire, although their service with the Company has been less than the specified period of two years (Cheers.) Secondly, it was announced that no medical examination would be imposed on the staff as a condition of their admission into the Civil Service of the Crown, a medical examination which would otherwise be necessary. Not only will that pledge be adhered to (it was qualified by possible exceptions in cases where the sick leave of individuals had been quite abnormal), but the other examination, the literary examination, which is necessary for ordinary entrance into the Civil Service, will be waived in the case of the employés of the National Telephone Co. Another paragraph in the Memorandum dealt with circumstances relating to the employés of the Company who had subscribed to the Company's Pension Fund, and it was declared that if it could be shown that by the closing of that Pension Fund, and by the substitution of a system of Civil Service Pensions, the general body of the staff would be placed in a substantially less favourable position, then the Postmaster-General would consider the expediency of allowing members of the staff to add two years to their service with the State for superannuation purposes. On further consideration I have determined, after consultation with the Treasury, that it is not necessary to impose the condition that was mentioned by Lord Stanley, and we shall not embark upon any inquiry whether or not the general body of the staff are disadvantaged by the transfer in respect of pensions, but we shall grant a general allowance of two years' additional service to those who desire to claim it. After all, it deos not seem to be a very fair thing that individuals should suffer merely on the ground that the general body of the staff do not suffer. The condition in itself is not really consistent with abstract principles o justice. But there is a further provision which will be found in the Telephone Transfer Bill which it will be my duty to introduce into the House of Commons in a few weeks' time, and I think this has not yet been publicly announced. We propose to allow an option to all those who now contribute to the Company's Pension Fund to assign their share in the Fund, if they so desire, to the Postmaster-General when the Fund is wound up, and in exchange they will be allowed to count all the years which they have spent in the service of the Company, and during which they have contributed to the Fund, as though they were years spent in the service of the State for pension and superannuation purposes (cheers. Those who have been original members of the Pension Fund, who were in the service of the Company before the Pension Fund was established will be allowed to count all the years they have spent in the service of the Company as though they were years spent in the service of the State for the purpose of a pension (cheers.) They will count as though they had been years spent in the service of the State in the offices to which these officers are transferred in the service of the Post Office. Those are the more important modifications which will be proposed, all of which as I have said, will be of advantage, and some of them greatly to the advantage of members of the Company's staff. There are other minor ones on which I need not dwell. Though comparisons are always odious certainly this is not the occasion on which to embark an any comparison of conditions of service which you will enjoy in the Post Office, and those you have enjoyed in the Company. I may perhaps mention only one fact. Many of those whom I see around me will, so I am informed, when they come into the employment of the Post Office, in their subsequent years have the benefit of one week's more leave in the year on full salary (laughter and cheers.) That alone, I think, will be a powerful attraction on the part of the new love compared with the old (laughter). One week in each year spent wherever it may be, on the South Coast, in Devonshire, in Wales or on the Continent—will, I trust, be largely devoted to singing the praises morning, noon and night, of the admirable arrangement of the Post Office Department (laughter). Gentlemen, I know there has been in your ranks anxiety for some time past as to the conditions that may await you in the new service to which you are going. There have been fears that the Telephone Company's staff may be, so to speak, thrown into the mass of the 200,000 employés of the Post Office, to find themselves lost there that they will become mere cogs in the wheel of official routine; th

Digitized by Google

their specialised skill may be unrecognised; that personal zeal and merit may be ignored among the great mass of the employés of the Post Office Department. Gentlemen, that will not be so. The Post Office is not ignorant of matters relating to telephony. It is well aware that it is a highly specialised, highly technical industry. We have passed the stage of the engineer of whom I have heard, who for years fervently entertained the belief that the difference between a telegraph wire and a telephone wire was that the telegraph wire was solid and the telephone wire was hollow (laughter). You will not find engineers of that kind when you come to the Post Office. We have learned much with respect to telephony. We know how difficult a business it is, how carefully every development needs watching, how vitally important it is that all the details of management should be conducted by men of zeal, capacity and efficiency—men who have a real interest in their task—and I can assure you that your knowledge and experience will not be allowed to be wasted when you come into the service of the State. The telephone work under the Post Office will be kept, in a very large measure, distinct from other Post Office work (hear, hear). There will be a much larger measure of differentiation than in the case of the telegraph, for example, from the remainder of Post Office work, and we feel sure by that means we shall best promote the interests of the public and best please the great commercial interests to whom the telephone service is becoming year by year of greater importance. Further, we shall follow the wise policy, as I regard it, that has been adopted by your Company of allowing a wide measure of discretion to local offices (cheers). We are aware of the danger of over-centralisation. The tendency in the Post Office in these days is decentralisation, and we do not propose to fall into the error of over concentrating at headquarters the management of telephone business throughout the country. We are quite alive to the importance of doing what, I believe, your directors have consistently endeavoured to do, and that is to encourage a high standard of scientific and technical attainment on the part of all officers of the staff, and every encouragement will be given in that direction. Nor need you fear that promotion in the Post Office will be determined by mere dead routine rules of seniority, and that merit will not be taken into account. It may be that in earlier years that was one of the faults of the Post Office system. It does not exist to-day; and although seniority must be always an element in the choice of officers for promotion, it is never regarded in the Post Office nowadays as the chief element, but merit, capacity, efficiency, zeal—these are the main considerations in the selection of officers for the higher posts (cheers). As it is in the other branches of the postal service, so will it be in the telephone branch, and zealous officers of the Company—and I know many of you are keen men, anxious to do your duty, your very best—need not fear when they come into the service of the State that their individual characteristics will be overlooked. They may feel sure that each man's personality shall count (cheers). Well, gentlemen, I know, for I have kept in touch with the movements that have been proceeding among the staff of the Telephone Company, that there has been some measure of anxiety among the officers, and it is not strange that men should feel uneasy if they think that their lives are going to be moulded this way or that by great external forces far beyond their control. It will be, indeed, a satisfaction to me if anything which I have said to-night, and, what is more important than words, if the deeds which will follow later, may in some degree relieve any uneasiness that has existed in your minds. I trust that the new will grow out of the old without any shock, with the minimum of hardship to individuals whose lives are affected, and indeed with great advantage to large numbers of them, and with the minimum of disturbance to the public, whom this splendid and prosperous corporation has served for so long (prolonged cheers).

Mr. S. Z. de Ferranti, who also replied, said: I feel there is little left for me to say. But I cannot do less than thank you on behalf of the guests here this evening for the kindness which you have extended to us in giving us this great hospitality. You have heard much of what will happen, or is likely to happen, in your future, much of what has been done by your great Company in the past. I cannot help, being here, with a great degree of sadness at the passing away, shortly to take place, of this great commercial undertaking. It is going to be merged, or rather absorbed, in the Post Office; but still, as I say, there is this passing away of your great industrial concern. This business has been conducted under much the same conditions as prevailed with the early electric lighting companies in this country. I have had to do with them in the past, and I know what it is to live and work under those exceedingly difficult conditions—conditions which greatly retard the progress and development of any industry. I know what it has been in the past to fight Parliaments before one could give a supply. I fully appreciate, from my own experience of that in London years ago, what the difficulties of the National Telephone Co. have been in many cases, and I can only feel sorry that such a great enterprise as the telephone should have been handicapped by an unfortunate necessity. There are many other difficulties, which you on the staff well know, which your Company has had to contend with. Those, however well you have been able to meet them, have largely absorbed your time and energies, and have taken you from the greater development which you might have accomplished if the Company had been working under more genial conditions (hear, hear). The incentive to do well in work very largely depends upon what we are going to get out of the results accomplished, and I must say that I regret that this transfer is being made to the Government, because in the service of the Government one can hardly expect to be working for a profit, and therefore one of the great human inducements is removed for doing the best work, for striving for the highest efficiency and making the greatest progress—namely, the greater reward that greater services will bring (cheers). As you have heard this evening, what many of you already knew, of the enormous development of this Company under the circumstances that have prevailed, or in spite of these circumstances. You have installed for the public more than half a million stations, an enormous and wonderful result. What do we find in the United States—truly, a country of more than double the population. Let us compare. Are they better people than we are, more enterprising? Do they deserve a better service? The fact is that they have seven million stations. And why is it they have gone ahead more, prospered more, and done more for the service of the community? It is because they have not had to sacrifice themselves, or to be sacrificed, for the benefit of the nation (hear, hear). You, gentlemen, have been handicapped in your work, and your great Company is coming to an end. Why? For the greater benefit of the State and of the individuals composing that State. That is at least what we are told. But is it really so? I only wish I could think that that will be the result which will be brought about. Gentlemen, I must again thank you for your hospitality to us, your guests, this evening. I wish you, I am sure, on behalf of the guests, every happiness and prosperity in the new position you will find in the future, and I must congratulate you upon falling into such sympathetic and able hands as those of the Postmaster-General, who will soon be your chief (cheers).

Mr. F. Douglas Watson then proposed "The Health of the Chairman." Mr. Anns, he said, had been their chairman at these annual gatherings on several occasions, and his urbanity in the chair, as on many other occasions elsewhere, was a great satisfaction to the staff. It was the last staff dinner that they would ever have, in that particular connection at all events, and there was a certain pathetic interest attaching to it on that account. He was sure they were all pleased to have had Mr. Anns in the chair (cheers).

The Chairman having briefly replied, a very pleasant function concluded. The speeches were interspersed with some excellent songs and humorous interludes.

BEST VOLTAGE AND SYSTEM IN RAILWAY WORK.*

BY C. R. DARBY.

Under the conditions which exist in North America, direct current and single-phase are applicable to either level or grade work; while three-phase will probably be limited to the latter where its regenerative feature of returning energy to the line may be of value. The relative economy of the different systems of electrification is dependent on the density of traffic and the character of power available, rather than on the length of the railway.

The principal conditions which determine railway equipment are: (*a*) Profile of road; (*b*) transportation required (i.e., weight of trains or seating capacity of cars); (*c*) frequency of trains; (*d*) length of individual runs or distance between stops; (*e*) schedule required; (*f*) length of railway to be electrified.

From a level country to a limiting grade of 1 to 1½ per cent. there will be little difference in the relative values of the systems. With steeper grades the conditions will be more favourable for alternating current. Heavy individual train units favour the alternating-current system with the exception of the locomotives; light trains or multiple-unit operation favour the direct-current system.

Infrequent service with a relatively small number of locomotives favours the alternating current; frequent service the direct current. With increase in number of trains, the direct-current systems gain relatively faster than the alternating current in economy of operation, due to relatively decreased sub-station operation, increased sub-station efficiency, and lower cost of equipment maintenance. It is therefore well to consider what the ultimate traffic density may be and select the system best suited to meet these requirements.

Variations in the distance between stops and schedule required will not affect the relative value of systems unless extreme requirements, such as high schedule speed with short runs, make the use of direct current imperative. For a similar character of service throughout, the railroad may be of any length without affecting the relative desirability of the various systems. What is suitable for the first 50 miles will be equally suitable for any extension.

An examination of the above variables will show that a change in the conditions to be met will radically change the relative economic value of the systems of electrification.

The single-phase system, by reason of the apparent simplicity of its elements and the utilisation of higher potentials for the contact conductor than is possible with the direct current, is admittedly very attractive. There is the other side of the question that the single-phase commutating motor is much higher in first cost and maintenance than the direct-current motor. Over this subject of alternating current single-phase *v.* direct-current systems there has been a great deal of controversy. It is my opinion that comparative results obtained up to the present time are in favour of direct current.

Desirable as would be a standard system for all classes of service, we cannot hope to establish such a standard should it impose an additional expense without adequate return. For trunk-line service a higher potential than 600 volts will unquestionably be used; 1,200 volts direct current will prove economical in some cases, but a still higher voltage is required to provide economically for the heavier

* Abstract of an article in the "Canadian Electrical News."

Digitized by Google

intermittent service. Whether this potential will be 1,800 or 2,400 volts direct current or 11,000 volts alternating current cannot be settled arbitrarily.

Interurban Railways.—The author next considers the interurban railway situation in the United States. The available schemes of electrification are: 600-volt direct current, 1,200-volt direct current, and single-phase, the three-phase being objectionable on account of the complications of the necessary double overhead distribution system.

The application of single-phase to new projects has been practically abandoned, there having been one or two new installations in the last three years. This arrested development of a system which for a short time held forth considerable promise has been brought about by a general recognition of its limitations. Experience has shown these to be: (*a*) Excessive weight of rolling stock; (*b*) excessive cost of rolling stock; (*c*) high cost of equipment maintenance; (*d*) increased power consumption; (*e*) rapid depreciation of motor; (*f*) rapid depreciation of car bodies and trucks; (*g*) increased cost of maintaining track and roadway. Moreover, it is recognised that any interurban road in the United States must be capable of operating over existing city tracks from 600-volt direct-current trolley, a condition which hampers the single-phase system on account of increased complications in the control system.

For interurban railways a potential of 1,200 volts direct current has been selected, because, with the motors wound for 600 volts, the car may be operated at the same speed from either 600 or 1,200-volt-trolley, by connecting the motors all in parallel for 600-volt operation, and two in series with two groups in parallel on a 1,200-volt section.

While comparing favourably with single-phase alternating current in the cost, operating expense, and reliability of the generating and distribution systems, the superiority of the car equipment of the 1,200-volt system gives this system a most pronounced advantage. The importance of this feature cannot be over-estimated. The 1,200-volt car equipment contains no radical departure from 600-volt practice, in design, construction or arrangement. The motor has the same rugged structure, the same capacity for overloads, and the same long life of bearings and brushes as its most successful prototype, the 600-volt motor. The control and auxiliaries are almost identical with a standard 600-volt equipment. The motors may be wound so that each will operate directly on 1,200 volts when in parallel, or so that two will be in series when at full speed. In the first case only half speed can be obtained on 600-volt sections; while, with the second arrangement, half speed, or, by paralleling the motors, the same car speed as on 1,200-volt, can be had on 600-volt sections. Both arrangements are in use, but in most cases two motors in series are preferable.

There will be an additional cost of operation and maintenance with the single-phase system for the items of track and roadway, due to additional weight of cars, car-shop expenses in providing greater facilities for shop inspection and repairs, and greater skill in superintendence of equipment. In a number of instances this has been found to amount to several cents. per car-mile. A conservative estimate would require at least ½d. per car-mile to be added for these items.

A comparison between the two systems brings out the fact that even for conditions selected as favourable to the single-phase system, the 600-volt direct-current system is the more economical, considering operation, maintenance and fixed charges. An examination of the elements which enter into the first cost and operation of a system will show at once that as the density of traffic increases there is a rapid gain in the relative advantage of the direct-current over the single-phase system.

The saving effected by the 1,200-volt direct-current system is so marked that a great increase in the adoption of this potential for this class of interurban railroad may be anticipated, and on the other hand it will not be surprising if the single-phase interurban system is entirely discarded in America, unless some improvement is made in the art and a more economical equipment made available.

LEGAL INTELLIGENCE.

National Telephone Co. v. Postmaster-General.

JUDGMENT.

The Railway and Canal Commission gave judgment in this case on Monday.

Mr. Justice A. T. Lawrence, in giving the judgment, reviewed the facts. By clause 3 of the agreement of Feb. 2, 1905, (he said) the Postmaster-General could (by notice to the company before Jan. 1, 1911) exclude from the purchase plant which he considered would be unsuitable for the Post Office service. If the company did not agree with the Postmaster-General they must obtain from that Court, before June 30, 1911, a decision that the plant objected to was "suitable," otherwise the Postmaster-General's objection was to prevail, and the plant objected to would remain the property of the company. The Postmaster-General had given 17 notices of objection which were said to be bad in whole or in part. For the Postmaster-General it was contended that he could object to any plant that he did not want. For the company, on the other hand, it was said that the clause had no such meaning, that it gave power to object only on the ground of the quality or character of the particular plant. The first thing that struck one upon this was that the word "unsuitable" pointed more aptly to quality than to quantity; next it was surprising that a vendor who had to keep his plant in use in order that it should be sold at all, should agree to leave it in the hands of the purchaser to provide as much other plant as he pleased, which would thus exclude his property from even "tramway terms." The agreement seemed to protect the Postmaster-General in very clear language from having any excessive plant imposed upon him. It was true that the company was a licensee only, whose property would be put out of use by the expiration of the licence. But he was a licensee who had performed a great public service and who was ready to agree to "tramway terms." What was now being done in providing new plant and new exchanges to take the place of the company's plant was practically to "scrap" the company's plant in the condemned exchanges. That did not seem to him to be just, and he should require clear words to induce him to hold that such a power was intended to be conferred upon the one party to this agreement by the other. The words did not seem to him to be clear: on the contrary, when all were read, and each received its natural meaning they failed to support such an argument. It was true the words "actual requirements" might mean real needs, but the telephone was a highly specialised instrument, and electrical science and its applications were constantly developing and producing new and ingenious devices, and he thought the words "suitable to the actual requirements" of the service seven years hence might very well apply to the quality and character of the particular plant and not to the sufficiency of some other and different plant—viz., that of the Postmaster-General—to perform the function of the company's plant. The argument for the Postmaster-General had assumed that "any kind" of *plant* meant plant of any quality and not plant of any description or variety. Having made that assumption he proceeded to treat that as showing that the word "requirements" meant "needs," for "kind" had already dealt with quality. It then said the test of those needs must be what the Postmaster-General would want for the combined business of the Post Office and the company. It then arrived at the conclusion that any plant of the company could be excluded from the purchase if the Postmaster-General had become possessed of the other plant of a similar description sufficient to serve the purpose. So that, however necessary the plant objected to might have been to the service of the company, however high its quality and modern its type, the Postmaster-General could reject it. That seemed to him not very wise or very likely bargain for even a licensee to enter into seven years before the expiration of his licence. But laying that consideration aside, it was not construction at all. When individual words might have two or more meanings one must not begin by assuming one meaning because it happened to suit him and disregard all others. Further, one must not treat as pedantic and technical a reference to the exact meaning of other words in the sentence merely because they rendered the assumption impossible. That was what the argument did: it said "the actual requirements of the telephone service of the Post Office on Dec. 31, 1911 meant "the prospective needs of the combined business of the company and the Post Office on the following day." No reason was assigned why that transposition should be made: but allusions to the public purse and the propriety of economy were gracefully substituted. With that provision the words of sec. 9 (1) of the London Agreement should be compared: There the date taken was "after" the determination of the licence, not before. Even then he did not think that any idea of excluding duplicate or surplus plant was shown, but there was in the section no in dispute a clear change of language, and that should in itself have some intention attributed to it unless that could be clearly negatived by reference to other parts of the agreement. It was admitted that, as applied to sub-clause (*a*), "suitable" referred to quality and not to quantity and that was clearly so, for in non-competitive areas, however excessive its quantity, all plant must be taken over if made according to schedule *i.e.*, according to the "requirements" as then formulated. No satisfactory explanation was afforded why, if that were so under (*a*) the should be a grouping of (*a*) and (*b*) together and an application of the same words but with a different meaning to (*b*); such grouping was only sensible and proper when it was made in order to apply one and the same proposition to both branches of the group. It was clear that when the parties had in mind any question of a surplus quantity they knew how to express their intentions in the plainest language, as could be seen from sec. 2 (1) (*d*) as to stores and (2) as to spare parts.

Digitized by Google

The next matter for consideration was the alleged invalidity of the notices of objection served upon the company by the Postmaster-General. There was no prescribed form of notice, and a notice was only bad upon the face of it when it failed to perform the functions for which it was required by the statute or agreement. The purpose which a notice was in the agreement under consideration designed to serve was to inform the company that the Postmaster-General considered certain property unsuitable and that he proposed to exclude it from the purchase. The mere notice effected its exclusion, unless the company within six months obtained an award that it was suitable. Any form of words which would enable the company to take into consideration the question and to decide whether it agreed with the Postmaster-General or differed from him would be sufficient. So long as the notice was sufficiently specific to enable the company and the Court to come to a conclusion upon the matter, it would be sufficient. That the property which it was proposed to exclude should be identified by the notice seemed to him to follow from the fact that it was a part which it suggested should be excluded from the whole; and that was supported by the language used in clauses 3 (1) and 3 (2). It was "such plant," &c., "as he considers will be unsuitable," and the award was to deal with that which had been "specified" in the notice of objection. The London notice (Part I.) seemed to him to comply with those requirements, though it might be that before the question of fact as to whether the property mentioned therein was or was not suitable some further particulars might be necessary. The same thing was true of the Abergavenny notice and of other notices. But when he turned to Part II. of the London notice, insofar as it purported to apply to plant other than that included in Part I., it seemed to him to be bad: it did not give one any idea of what plant it was or where it was situate, except that it was in the London area. It gave grounds of objection without stating the property to which they were alleged to apply. It was one thing to specify a piece of property and another to specify a quality to which one objected. Whether any particular piece of property was open to one or more of those grounds of objection was a matter about which opinions differed, and until the property was identified the question could neither be considered nor determined. The notice relating to non-competitive areas was bad for those reasons. It was no answer to say that it would have been difficult and troublesome to give a notice mentioning the plant objected to. The difficulty of duly exercising a power was no excuse for not doing so if the rights of other parties were affected thereby. The company disputed that any of its property was open to those objections. That form of notice would exclude it all from the purchase unless and until the company proved to the Court that each particular part had not the defect. That was to change the onus in a manner not justified by anything in the agreement, and to read "such plant as he considers unsuitable" as satisfied by a notice which was so framed because he did not know the facts and did not desire the trouble of ascertaining them—that although the Postmaster-General had the right under the agreement to make the company furnish him with all the information he might reasonably require.

Mr. Cathorne-Hardy delivered a judgment to the same effect.

Sir James Woodhouse dissented, and gave reasons for holding that the notices given by the Postmaster-General sufficiently described the property he did not desire to take, and that the agreement did not require him to purchase duplicate plant if he considered that the telephone service could be carried on efficiently with the buildings and plant already at his disposal. He thought that from the business point of view it would be misreading the true intention of this agreement to hold that that notice was so imperfect as to render it invalid, and that complete justice could be done between the parties on the merits without placing that strict interpretation upon it. He thought the word "unsuitable" when taken in collocation with the words which followed had, and according to the scheme of the agreement was intended to have, a quantitative as well as a qualitative meaning. The test was the Postmaster-General's requirements—in other words, his "needs"; and the standard of suitability for his actual requirements in the circumstances of these areas is the character or quality of the plant. He thought "requirements" and "needs," and "actual" referred to those at the time of award in contradistinction to the requirements of the future. He also thought that the form of the notice was valid, and he thought the Postmaster-General was entitled to judgment on both points.

Sir Alfred Cripps, K.C., said that, in substance, the order that was to be drawn would be one granting the application asked for by the company under 2c, and under another clause the company asked that any plant of suitable character for the actual requirements of the telephonic service of the Post Office on Dec. 31, 1911, should be taken over by the Postmaster-General.

Mr. Justice A. T. Lawrence: That is the point upon which Sir Jas. Woodhouse differs from the rest of the Court.

Sir Alfred Cripps: I am anxious that we should have our argument directed to it, in which we ask for a declaration that

"That plant of the company suitable in character for the telephonic service of the Post Office on Dec. 31, 1911, is not rendered unsuitable for such requirement because the Postmaster-General on that date had in his possession other plant suitable for such service."

Mr. Justice A. T. Lawrence: Is there any objection to that, Mr. Isaacs?

Sir Rufus Isaacs: We have your lordships' judgment. We know what the agreement was.

Sir Alfred Cripps pointed out that under the agreement between the parties it was necessary to have a decision of that Court upon the question submitted to them by the end of June.

Sir Rufus Isaacs said the Government would extend the time provisionally to the end of July. He intimated that it was his intention to appeal against the decision just recorded.

Sir Alfred Cripps asked that the appeal should be expedited as far as possible, as there were many matters to come before that Court before the extended period of July 31, and, so far as he could see, the discussion of those matters would occupy perhaps a fortnight.

Mr. Justice A. T. Lawrence: We will give you as early a date as possible after you have obtained the judgment of the Court of Appeal. I am certain the Court of Appeal will give you the earliest day possible, and I hope you will endeavour to classify the matters in dispute so closely that we may be able to dispose of them rapidly.

Upon the application of the Attorney-General the Court of Appeal (the Master of the Rolls and Lord Justices Buckley and Kennedy) yesterday (Thursday) agreed to expedite the hearing of the appeal from the above decision of the Railway and Canal Commission and June 14 was fixed for the hearing.

"Z" Electric Lamp Mfg. Co. (Ltd.) v. Osram Lamp Works (Ltd.)

On Friday an application was made to Mr. Justice Neville by plaintiffs for an interim injunction to restrain defendants from threatening by circulars, letters or otherwise, plaintiffs (or any other person or persons whereby plaintiffs might be aggrieved) with legal proceedings or liability in respect of any alleged infringements of defendants' letters patent in respect of the manufacture, use, sale or purchase of incandescent electric lamps manufactured or sold by plaintiffs.

Mr. T. Terrell, K.C., for plaintiffs, contended that defendants were not acting with bona fides. They had commenced actions against purchasers and users of other lamps, alleging infringements of their patent Osram lamps, but would not bring an action against plaintiffs, who were willing to fight such an action and to contest the validity of defendants' patents.

Mr. Astbury, K.C., for defendants, submitted that the action could not be maintained. Defendants were within the proviso of sec. 36 of the 1907 Act. What they were doing was to tell the world that plaintiffs' lamps were an infringement of their patent, and that, he submitted, they not only had a right to do but was what they ought to do. They had commenced actions against several persons and firms who were selling or using lamps manufactured or sold by plaintiffs on the ground that such lamps were infringements of the patents under which defendants manufactured and sold Osram lamps, and were prosecuting the actions with diligence. There was no foundation for the allegation of want of bona fides. The several actions were being defended and the solicitors on the record for defendants in those actions were the solicitors on the record for plaintiffs in the present action. If plaintiffs would waive the question of retainer of Mr. Walter, K.C., defendants would issue a writ for infringement against plaintiffs at once.

Mr. Terrell said his submission was that these actions were not brought for the purpose of trying the question between the parties, but were brought against persons who were not likely to defend them. These lamps were made in Germany from 1905 to 1908 and subsequently in England. It was not until plaintiffs' alleged infringement of their patents that defendants commenced the threats complained of. They had challenged the defendants to bring an action against them and they had not done so.

Mr. Justice Neville said he saw no ground for supposing that the actions which defendants had commenced were not bona-fide actions or that defendants would not prosecute them diligently. No case of prejudice had been made out, and the motion must be dismissed with costs.

Humphreys v City of London Electric Co. (Ltd.)

On Wednesday the Court of Appeal (the Master of the Rolls and Lords Justices Buckley and Kennedy) heard this appeal of the applicant from the award of the judge of the City of London Court under the Workmen's Compensation Act.

Mr. Boxall, K.C. (for appellant), said that applicant was employed by respondents as an electrical fitter, and in November, 1908, he had an accident, his thumb being cut by an electric arc lamp which resulted in several operations, and finally half his thumb was amputated and he had now lost the entire use of his right hand. For some time applicant was permanently incapacitated from work, but at the time of the arbitration he had obtained employment with respondents in a different capacity and was now employed by them as a watchman, which involved day and night work. In his former employment the applicant's wages were 32s. 6d. a week for 50½ hours work a week. As a watchman he had to work 68½ hours a week and his wages were 25s. a week. Applicant's contention was that the judge in the court below should have made an award in his favour for 7s. 6d., the amount he had lost by reason of the accident, but the judge only awarded him half that amount. He (counsel) contended that applicant was entitled to an award for 7s. 6d.

Without calling upon counsel for respondents their lordships dismissed the appeal, holding that there was no point of law involved upon the appeal and that they could not interfere with the finding of fact of the learned judge in the court below.

Glasgow Tramways Assessment.

On Monday Sheriff Gardner Millar delivered his reserved judgment in the appeal of Glasgow Tramways Committee against the assessment of their undertaking.

In the course of his judgment the Sheriff said that he had found great difficulty in the case. It was an appeal by the tramways department

Digitized by Google

against the assessment of their undertaking under six heads (police, sanitary, statute labour, sewage, roads and bridges, and parks), and involved rates amounting in all to the yearly value of £12,514. 8s. 3d. After referring to the statutes imposing the rates he said there was no doubt appellants' undertaking, so far as it consisted of the lines upon the street, fell under the description of "lands or heritages," but the question was whether it was a railway within the meaning of the statute, so that its yearly rent or value should be deemed to be one-fourth of the amount entered upon the valuation roll of the city. It did not seem to be of much importance to trace the derivation of the words "railway" and "tramway," because in the course of time these undertakings might be so differentiated in character as to deprive the original terms of any significance. Nor did he think that the fact that for the last 39 years appellants' undertaking had been considered by the assessor to be a railway, and so entitled to the restriction applicable to a railway. Appellants' counsel maintained that a practice so long continued was not lightly to be set aside, as it showed the meaning that by common consent all parties put on the words. He referred to the decision in Laird & Sons v. Clyde Navigation Trustees and compared the physical characteristics of railways and tramways. The ordinary citizen knew perfectly well the distinction between a tramway and a railway, and, in ordinary language, would never think of confusing the two, and if it was competent to consider the ordinary use of the words in common parlance, that seemed to the Sheriff a strong point in respondents' favour. Another consideration arose with regard to the reason why the restriction of valuation should be allowed in favour of railways, and whether the reason for it was equally applicable to tramways. The question had arisen in England in connection with a statute expressed in similar terms to that of the statutes which they were now considering—in the case of the South Wales Railway Co. *v.* Swansea Local Board of Health, and in that case it was said that the general scheme of the enactment was that the occupiers of the classes of property most benefited by the expenditure of the district rates should be liable to be rated at a higher rate than the occupiers of the classes less benefited at the lower rate. It was plain that the railway company, in so far as the road upon which their line was laid was concerned, got less benefit from the rates applied to such matters as police, lighting, maintenance of roads, &c., than other classes of heritage, and accordingly they were only assessed at one-fourth of their yearly valuation for those purposes. But it was difficult to see why a tramway line did not get the same benefit as other heritages from the expenditure of the rates upon lighting, police, maintenance of roads, and even sewage. If they did get the benefits like any other heritage from the expenditure of the rates there was no reason why the Legislature should have granted a particular exemption in their favour as compared with other ratepayers in the district. After considering those arguments, he should be inclined to hold, apart from authority, that the words in the statute "the line of any railway constructed under the powers of an Act of Parliament for public conveyance" did not apply to the case of a tramway, and, therefore, appellants had failed. He referred to English and Scottish decisions, and concluded by saying that upon the whole matter he was of opinion that the appeal should be dismissed and the assessment affirmed, but without costs.

Conolly Bros. Ltd.; Wood v. The Company.

On Tuesday Mr. Justice Warrington heard a motion for judgment in default of defence in this case. Plaintiff was a debenture holder, and in giving formal judgment in a debenture holder's action his lordship directed a special enquiry as to priority of encumbrances.

PARLIAMENTARY INTELLIGENCE.

ROTHERHAM CORPORATION BILL.

This Bill came before the Local Legislation Committee of the House of Commons on Tuesday.

Mr. RAM, K.C., for the Corporation, explained that the bill dealt with a variety of subjects, and he proposed first to deal with the tramways scheme. The Corporation proposed to lay down a tramway. They also asked power to provide and run motor omnibuses over specified routes. There were also alternate proposals for motor buses or trackless trolley vehicles. The buses would not pay rates, but the trackless trolleys would upon the apparatus which would have to be laid down. The outside authorities were not opposing the scheme.

Ald. D. L. WINTER said their tramway system showed a net profit of £3,000 on a capital of £150,000.

Mr. H. CROSS, borough electrical engineer and tramways manager, gave estimates of the cost of the trolley equipment as follows:—Kimberworth to Thorpe, £11,004. 19s.; borough boundary to Maltby, £20,340. 19s.; Canklow terminus to Treeton, £6,368. 9s.; total, £37,714. 7s. He estimated the profits at £20,317.

On Wednesday the evidence for the Corporation closed and the Committee ordered the room to be cleared, and, on the parties being readmitted, the Chairman (Mr. Helme) announced that the Committee approved of the provisions relating to the proposed tramways, trackless trolley service and omnibuses.

Mr. LLOYD, K.C., who appeared for the Great Central Railway Co. against the Bill, protested that the Committee had heard neither him nor Mr. Bidder, for the Midland Railway Co., in opposition. They would reserve their right to oppose the Bill in the House of Lords.

Ultimately the Committee decided to give powers for trackless trolleys either from Jan. 1, 1912, or six months after the issue of the Board of Trade certificate to Leeds Corporation for their trackless trolley service.

COAL MINES BILL.

Further progress with this Bill was made during the week by Standing Committee B of the House of Commons.

On Tuesday the Committee considered clause 32, which provides that only locked safety lamps shall be used in seams where the air-current in the main return airway is found to contain more than one-half per cent. of inflammable gas.

Col. HUCKMAN moved to permit the use of electric lamps in such seams, but the amendment was withdrawn on the understanding that the question of lamps in main haulage roads would be reconsidered.

Mr. MARKHAM moved that the section should be amended so as to read that only locked safety lamps should be used in any mine.

After discussion the amendment was negatived without a division.

National Telephone Staff.—In reply to a question in the House of Commons on Friday, the Postmaster-General stated that on the transfer of the National Telephone Co.'s undertaking members of the staff would enjoy the advantages and be subject to the conditions of the rank or grade in the Post Office service to which they were admitted. It followed from that that transferred officers would obtain pensionable status if they were placed, either at once or at some subsequent date, in positions which were pensionable under the ordinary rules of the Civil Service. The fact that an officer contributed to the Company's pension fund would not affect the question of this status in the Post Office, but he anticipated that almost all the officers pensionable by the Company would, on transfer, be placed in pensionable offices, while a large number of officers whose posts under the Company were not pensionable, would be transferred to grades in the Post Office service which enjoy pension rights.

Mica Condensers.—In a recent issue of the Bulletin of the Bureau of standards Mr. H. L. Curtis discusses the use of mica condensers as standards of capacity. The following is a summary of the points dealt with: (1) The various methods for measuring capacity with alternating current and continuous current are discussed, and the best methods to use when mica condensers are to be measured are indicated. (2) A method is given by which the temperature coefficient of a mica condenser may be made very small, at most a few parts in a hundred thousand per degree. (3) The effect of changes of the atmospheric pressure upon the capacity are shown to be small though in some cases they are not negligible. (4) An explanation of the change of capacity with voltage, which is observed in the case of silvered-mica condensers, is offered. (5) Condensers which are kept in a vacuum and maintained at constant temperature can be relied upon to a few parts in a hundred thousand. Such condensers are somewhat more stable than condensers which are maintained at constant temperature, but subjected to the ordinary fluctuations of atmospheric pressure. Condensers exposed to the ordinary changes of room temperature show unaccountable variations of the capacity of two or three parts in ten thousand. (6) It is shown that, taking the measured values of the specific resistances of mica and paraffin Maxwell's theory of a stratified dielectric does not account for the absorption actually observed in the case of a mica condenser. This theory is then applied to alternating current measurements, and it is shown that, according to this theory the loss of energy per *second* in the dielectric is nearly independent of the frequency, whereas measurements show that the loss of energy per *cycle* is almost independent of the frequency. The conclusion is drawn that this theory alone will alone not explain the phenomena of absorption. (7) The capacity of a condenser with alternating current of infinite frequency is shown to be the same as the capacity with continuous current when the time of discharge is infinitely short. This capacity is called the geometric capacity, since it is a function of the dimensions and dielectric constants of the dielectrics.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Aberdeen.—The report of the city electrical engineer (Mr. J. Alex. Bell) on the recent stoppage of supply was presented to the Electricity Committee last week.

Mr. BELL stated that the breakdown was due to the following three causes:—(1.) The drawing of a heavy current to a faulty cable in Union-street due to a pickhole in the cable; (2.) The overloading of the boiler plant at the time; (3.) Owing to one of the mechanical stokers failing to operate, the steam was reduced to such a degree that it was found necessary to shut down the station until the mechanical stoker could be put right, and steam pressure brought up again.

Accrington.—Some time ago the assessment of the electric tramways was increased from £800 to £1,650, by Haslingden Union Assessment Committee, but the dispute was referred to the arbitration of Mr. Thos. Wainwright, who has now issued his award, fixing the assessment at £2,544.

Barking.—Application has been made for sanction to a loan of £11,000 for the electricity undertaking.

Beckenham.—At the last Council meeting the Electricity Committee reported that the L.G. Board had sanctioned the raising of a further £5,000 for "free" wiring.

As 11 months had elapsed since tenders for that class of work were raised, they recommended that fresh tenders be issued; and in the meantime the work to be continued through local contractors at revised prices, subject to the resident engineer, Mr. J. E. Tapper.

The Clerk submitted tables showing the effect of the expenditure of the sum of £5,000, and, arising out of the report, the Committee recommended that in future the Council, in both new free wired installations and on changes of tenancy, provide the equivalent of carbon lamps only, the consumer being required to pay the difference between 9d. (the value of a carbon lamp) and the price of the particular metallic lamp selected.

Mr. A. H. Dykes said that as he had felt it his duty to severely criticise some of the figures which had been put before them by the Committee during the past two or three years, he was now pleased to say that they were all making a small profit. He thought that that was exceedingly satisfactory, and a great improvement on what they had been doing, and that everyone concerned should be congratulated upon it. He considered it right, however, that it should be pointed out that those figures were based upon the first cost of free wiring, which was 25 per cent. below what they had been paying: and those figures showed that had they continued to pay the old price, instead of making a profit for the remaining eight years, they would have made a loss of £150 a year.

Belfast.—The agreement for the taking over of the undertaking of the Cavehill and Whitewell Tramways Co. has been approved. On and from to-day (Friday) the Corporation will manage the tramways. There will be a through connection between the city system and the new lines.

Bradford.—An inquiry was held on Tuesday into the application of the Corporation for sanction to borrow £60,000 for extensions of the electricity undertaking.

There was no opposition and evidence was given by the town clerk (Mr. F. Stevens) and the city electrical engineer (Mr. T. Roles). It was explained that the loan was required chiefly for mains and for the extinction of debt already contracted. An appeal was made for the longest possible period for repayment.

Bridlington.—It was reported to the Council on Wednesday that the report on the past year's working of the electricity department showed a profit of £1,000, an increase of £369.

Bromby and Frodingham.—An inquiry was held on Tuesday into the Council's application for sanction to borrow £1,100 for street lighting.

It was stated that the streets were at present lighted by oil lamps, and as this would be too costly, a scheme for supplying electricity for street lighting had been prepared, although a former project for public and private supply had been rejected. It was now proposed to take electricity from the Frodingham Iron & Steel Co.

Coronation Illuminations.—Fulham (London) Council will charge 2d. per unit for Coronation illuminations, plus 5s. inspection fee.—Ilkeston Electricity Committee have decided to illuminate Sunnyside Wood in Coronation week.—Warmley Rural Council will celebrate the Coronation by inaugurating electric lighting in the Kingswood district.

Islington (London) electricity department have issued a folding card on which they offer to supply current for Coronation illumination purposes at a fixed rate equivalent to 1d. per unit, dependent upon the number of lamps installed and the hours of illumination, plus a fee of 5s. for connection, &c.

Crayford (Kent).—The Parish Council have asked Bexley, Erith and Dartford Councils to quote terms for supply of electricity for street lighting.

Croydon Corporation Tramways.—At the meeting of Croydon Council on Monday the Tramways Committee submitted a lengthy report from the tramways manager (Mr. T. B. Goodyer) on the subject of fares generally, and the following recommendations of the committee were, after full discussion, unanimously adopted:—

(*a*) That no system of ½d. fare stages be adopted, (*b*) that no alteration be made in the present ordinary fares, (*c*) that the workpeople's fares remain as at present, (*d*) that the 1½d. fare stages be not adopted, and (*e*) that the fare stage distances remain as at present.

The recommendation of the Tramways Committee, against the views of Mr. Goodyer, to re-open the Whitehorse-road route (which, from previous operation, had resulted in an annual loss of over £2,000) was, on an amendment that the line should not be worked until the rates had been reduced, lost by 24 to 21 votes.

Doncaster.—The L.G. Board have approved a scheme of sewerage and sewage disposal prepared by Messrs. D. Balfour & Son, of London and Newcastle-on-Tyne, for the parish of Adwick-le-Street, in which is included the model village of Woodlands. The sewage from a portion of the district is to be pumped from a storage tank by means of electric motors and pumps to the disposal works where it is to be treated.

Edinburgh.—The Electric Light Committee are considering a request of the Merchants' Association for a reduction in the charge for electric current for industrial purposes.

The Electric Lighting Committee recommend the Council to reduce the price of electrical energy to 2¾d. per unit (a reduction of ¼d. for private lighting.

Electricity in Gas Works.—At a meeting of Dundee Gas Committee on Monday Convener Clark gave an explanation of the introduction of electrical stoking plant at the gas works.

The cost of the plant is estimated at £3,900, and in order that the members of the Council might make themselves familiar with the matter Mr. Clark said he had arranged to furnish them with information regarding the latest types of stoking plant.

It was also reported to the Electricity Committee that the cost of the second instalment of the mechanical stoking plant for the electricity works would be £396.

Fulham (London).—Mains are to be extended to the Crabtree Farm estate at a cost of £1,164.

Heston and Isleworth.—The Electricity Committee, acting on the advice of their electrical engineer (Mr. P. E. Rycroft), have decided not to enter into a contract for the supply of metal filament lamps for the present owing to the unsteadiness of quotations, but to buy in the open market.

Three 50 c.p. lamps, from each of seven different makers, had been tested and none had failed. The contract with the British Economical Lamp Co. for maintenance of street lamps, would expire on June 30 Hitherto maintenance had cost £165 per annum. Two fresh quotations had been received which showed that the cost for the 400 posts would be only £115, and it was agreed to invite further tenders when the present contract expired.

Hull.—An inquiry was held on Wednesday into the application of the Corporation for sanction to borrow £99,000 for extension of the electricity works.

The city electrical engineer (Mr. H. BELL) gave evidence and stated that the total capacity of the existing plant was 6,500 kw. and there was need for extensions to anticipate the increasing demand, especially for power.

Ilford.—An unopposed inquiry was held last week into the application of the Council for sanction to borrow £8,070 for their electricity undertaking.

Light Railways.—Hertford County Council are applying for an order to authorise the construction of about ¾ mile of tramways in Watford, as a deviation of railway No. 1 authorised by their 1908 order.

Birmingham Corporation are applying for an order to authorise the construction of a line commencing partly in Worley (Oldbury) and partly in the City of Birmingham and ending in Smethwick.

Digitized by Google

Newport (Mon.)—The Council propose to equip offices, showrooms and stores for the electricity and tramways departments at a cost of about £2,000.

Overhead Telephone Wires in the City.—At the meeting of the Court of Common Council last week the Streets Committee reported the receipt of a letter from the solicitor of the General Post Office (Sir R. Hunter) on the subject of the acquisition of the plant of the National Telephone Co.

The letter stated that the Postmaster-General had objected to purchase the overhead plant connected with certain exchanges in the City, and the Corporation was asked to support the case of the Post Office before the Railway and Canal Commissioners.

The committee recommended that Mr. Deputy MORTON, M.P., should be requested to give evidence in favour of an underground system of telephones.

Ald. Sir GEORGE WOODMAN asked whether Mr. Morton's evidence would be confined to expressing the opinion of the Corporation upon the merits of the underground system as compared with the overhead one, or whether he would have an opportunity of expressing any other views. It seemed extravagant and expensive that the whole of the overhead system should be scrapped at once. Would Mr. Morton express any view on behalf of the Corporation as to the dispute between the National Telephone Co. and the Post Office? There were many questions involved, though probably the Court would agree that the underground system, if it could be installed with the minimum of discomfort to the City, would be far superior. Would Mr. Morton have an opportunity of getting an undertaking from the Post Office on the question of rating? At the moment Government departments paid only what they cared to pay, whereas the National Co. was assessed as a trading company upon its profits. Would it be possible to obtain some assurance that the matter would be dealt with equitably? Then there was the damage which would accrue by the pulling down of the overhead wires. He was by no means certain that the matters could be raised upon the report, but he wanted an assurance that the whole of the interests of the Corporation and of telephone users would be safeguarded.

Mr. JOSIAH GUNTON, chairman of the committee, said Mr. Morton was conversant with the whole matter.

Mr. W. W. GREEN thought the question should be watched by the Special Committee. Owners of property would be greatly affected. He moved accordingly.

Mr. Deputy MORTON did not think that many of the points mentioned arose in connection with the evidence he was asked to give. He was simply to express the view at which the Corporation arrived in 1905 to the effect that, subject to conditions, it was in favour of an underground system because it was the only one that could be properly worked. The Corporation had always submitted that there should be conditions, and that the price for the flat rate should not be above £10 per annum. That he had put in his proof of evidence. The Streets Committee had always been anxious to get an efficient telephone service for the City at a fair rate.

Mr. Deputy WALLACE seconded Mr. Green's amendment that the whole question should go to the Special Committee.

On the suggestion of the LORD MAYOR, the Streets Committee were added by the mover and seconder to the reference. The matter was left with the Streets Committee, with instructions to confer with the Special Committee. Mr. Ernest Lamb and Mr. Green were added to the committee.

Petrol-Electric Car on Great Central Railway.—The Great Central Railway Co. have recently placed an order with the British Westinghouse Co. for a "petrol-electric" car, which will shortly be put on the tracks in the London district for its trials under the direct observation of the general manager (Mr. Sam Fay), preparatory to going into service on a branch line.

The car is of the general type developed successfully by the Westinghouse companies on the Continent, will seat 50 persons, and will be capable of hauling two trailers, seating 50 more, at an average speed of 30 miles per hour on the level.

Pontardawe.—The Council have asked Mr. John Morgan to prepare a fresh report on the question of electricity supply in the district.

Reeth (Yorks.).—Next winter this village will be lighted electrically, as Mr. Burton, of Askrigg, Wensleydale, has contracted to light the village with metal filament lamps totalling 1,050 c.p. for five years at £20 per year. Water power is to be utilised in generating electrical energy.

St. Pancras (London).—The question of the charge for outside shop lighting has been under the consideration of the Electricity Committee.

The chief electrical engineer (Mr. S. W. BAYNES) reported to the committee that at present the approximate revenue from outside private lighting is £,5000 per annum, but he thought that, unless the charges were lowered, this sum would decrease. The committee have, therefore, decided, subject to the usual sanction, that the flat rate charge for current supplied for outside frontage lighting be 3d. per unit as from the June quarter, and that rentals be charged for separate meters required to register the supply.

Stepney (London).—St. George's town hall is to be wired during the summer vacation at a cost of £250. Application is to be made to the Board of Trade for a provisional order scheduling the sites of the Council's generating and sub-stations as "statutory" sites.

Stoke-on-Trent.—An inquiry will shortly be held into the Council's application for sanction to a loan of £60,000 for the erection of a new power station, and application has been made to the Board of Trade for consent to supply electricity on the e.h.t. three-phase system in the borough.

Warmley.—The Rural Council will inaugurate in Coronation week a scheme of electricity supply for the Bitton district.

Mr. King Smith (owner of Bitton Mill) will supply current and provide lamps and wires for an annual sum, and sufficient money has been voluntarily subscribed to pay for seven years' lighting. Overhead wires on poles will be used.

Wireless Telegraph Notes.—A very circumstantial statement has again appeared in one of the London morning papers as to communication being effected between the Eiffel Tower, Paris, and the Glace Bay station of the Marconi Company in Canada. It will be remembered that previously statements of this kind have been made, only to be categorically denied the following day. The particular statement published this week is to the effect that the Marconi station at Glace Bay has been in communication with the Eiffel Tower in Paris. The message from the Eiffel Tower to Glace Bay was also picked up by the station at Dakar, West Africa, and was said to have been relayed from this point direct to Glace Bay. Finally it is stated that the two stations were in perfect communication for fully an hour. This entire circumstantially stated piece of news was denied in toto in a few hours by the Marconi Company.

A correspondent of the "Financial Times" has been writing on the subject of wireless telegraphy with special reference to an installation in one of the potash mines of the Harz mountains in Germany, where for 1½ miles a service of wireless communication is established at a depth of about 1,600 ft. below the surface with satisfactory results. Our contemporary's contributor suggests that such a system might easily be adopted in many of the coal mines in Great Britain, where he considers the advantage is important and involves so little cost that "its general adoption should be considered."

COLONIAL AND FOREIGN NOTES.

Canada.—The Canadian Light and Power Co. have placed before the Dominion Government a project for the erection of hydro-electric works at Cedar and Coteau Rapids, on the St. Lawrence river, about 25 miles above Montreal, at a cost of from $15,000,000 to $20,000,000. It is estimated that 500,000 H.P. can be obtained.

Canary Islands.—An application for a concession for an electric tramway between the Barrio de San José and the centre of Las Palmas has been lodged with the Spanish Government by the Soc. Anon. Banco di Castilla.

Customs Duties.—According to recent decisions, car fittings for tramway and railway carriages (blinds, rattan seating, &c.) imported into British South Africa are subject to a duty of 15 per cent., and insulating paper, leatheroid and cloth for eletrical purposes are subjects to 3 per cent. In both cases British goods have a rebate of 3 per cent.

Egypt.—Imports of electrical machinery into Egypt in 1910 were valued at £113,771, of which £51,929 was from the United Kingdom, compared with £62,949 and £22,479 respectively in 1909.

Hayti.—Port-au-Prince is now lighted by electricity, the first time artificial lighting has been adopted.

A concession has been granted for the construction of a narrow-gauge electric tramway from Port-au-Prince to La Coupe, but construction work has not yet commenced.

Holland.—Exports from Flushing to the United Kingdom in 1910 included 11 million brass caps for incandescent electric lamps, compared with 7 million in 1909 and an average of 7,400,000 per annum for the five years 1906–1910.

Italy.—The report of Consul de Zuccato on the trade of Venice for the year 1909–10 states that the Germans continue to hold the trade they have captured and which was formerly in British hands, chiefly in machinery, electrical appliances, &c. The hydro-electric industry for long-distance transmission continues to develop, and several fresh schemes are under consideration.

The Soc. Varesina per Imprese Ellettriche have secured a concession for an electric tramway from Varese to Bobbiate.

Java.—M. Huber has applied for concessions for electric tramways from Groedo to Sourabaya and from Willemsplein to Sourabaya harbour.

Norway.—The following information is given in reports for 1910 by British Consuls in Norway:—

There was a brisk importation from Germany of porcelain insulators, zinc plates, copper wire, water-power machinery, dynamos and electric

Digitized by Google

cables. The export of a consignment of electrically-smelted copper is reported from the Birtavarra mines.

Several works for the electric smelting of iron ore and one for the electric production of steel from broken-up vessels, &c., have been either under construction or planned in 1910. At Arendal there are a number of iron mines yielding excellent ore, and the Arendals Fossekompagni has been started by Mr. S. Eyde, with a capital of about £225,000, for the manufacture of steel electrically. Near Arendal there is also a factory called the Electrum Metallurgisk for making ferro-silicium. About 100 tons of excellent steel were electrically produced in a 1,000 H.P. furnace by the Alb. Hoerth process at Jössingfjord, between Flekkefjord and Egersund. About 800 tons of aluminium were produced in 1910 at Vigeland's Works, near Christiansand, where imported aluminium oxide is reduced by an electrical process. The Norwegian export of ferro-silicium was about 5,000 tons. The Sundlökken electrothermic zinc factory near Hatslund produced about 4,000 tons of electrically refined zinc, the raw material being partly foreign raw zinc and partly ore imported chiefly from Australia and Greece. The total export of calcium carbide was only about 50,000 tons, manufacture being reduced owing to over-production abroad, while the export of cyanamide was some 4,500 tons. The value of these products was estimated at about £650,000.

Another new development is the Electric Ore Smelting Co., in Tyssedal, near Odda, on the Hardangerfjord. The concern is expected to be in working order about the spring of 1912. Besides the electric smelting of iron ore, which it will commence with 2,500 H.P., the company will erect a station for smelting zinc ore, for which 3,000 to 4,000 H.P. will be used.

In the early part of the year Aktieselskabet Svælgfos ordered the entire electrical outfit for the Lienfos power plant for the production of nitrate of calcium. The order comprised four three-phase generators of about 9,500 E.H.P. each, and two exciters of about 500 H.P. each, with switch-gear, &c.

The outstanding feature of 1910 was the starting of the electro-steel industry by the Tinfos Papirfabrik, Notodden, which possesses, besides its two wood-pulp mills and an electrical power plant for 8,500 H.P., together with a saw and planing mill, electrical smelting works for smelting iron ore. By way of experiment, they started in January, 1910, with 500 H.P., and during the year they produced about 450 tons of pig iron. A separate limited company has now been formed, under the style of Tinfos Jernverk, with a capital of £56,250, to continue the smelting works, which are the first of their kind in Norway. It is intended during 1911 to build and start smelting furnaces for 5,000 H.P., which are expected to be in full swing in the course of the summer. During 1912, when the next 5,000 H.P. will be available, the smelting furnaces will be increased and the rolling mill and steel works erected. Another 5,000 H.P. may eventually be added. The ore is brought from the Langö, near Kragerö. At the Ulefos Jernverk the owner (Mr. D. Cappelen) has an electric furnace for iron smelting, and the accessories for a second furnace have been ordered.

Porto Rico.—A consular report states that plans are being prepared for doubling the electric tramway between San Juan and Rio Piedras.

Russia.—Chernikov municipal authorities have applied to the Council of Ministers for permission to borrow about £10,500 for the purchase of electrical machinery, &c.

South Africa.—The raising of £120,000 by Salisbury (Rhodesia) Municipality for the provision of electricity and water supplies, &c., has been authorised.

Spain.—A consular report on the provinces of the Asturias, Galicia and Leon states that the last negotiations for electrifying the Corunna tramways have fallen through, but a British firm is examining the scheme. The Vigo city electric tramway scheme has been given up. At Vigo harbour an electric crane capable of dealing with 130 tons of coal per hour has been erected.

Spain.—The Soc. Anon. Iberia Concessionaria have applied to the Public Works Department, Madrid, for a 60 years' concession for an electric tramway from Porrino to Vigo.

Switzerland.—An 80 years' concession has been granted to Herr Frederic Hoffmann and Dr. F. Volmer for constructing a narrow gauge electric railway from Worblaufen to the railway at Worb or to the Berne and Thorne line, with a branch from Schermen to Berne. The cost is estimated at £64,552.

E. Frote & Co. of Zurich have a concession for a narrow gauge electric railway, 50 miles in length, from Coire to Bivio. The cost is given at £340,000.

Transvaal Power Scheme.—At the meeting of the Tweenfontein Colliery, Ltd., last week the chairman (Lord Oranmore and Browne) referred to the arrangement with the Transvaal Hydraulic Power Syndicate by which the latter were to erect an electric power station and certain factory and to purchase from the colliery about 25,000 tons per month of different classes of coal.

He said that it was only on Oct. 27 last that the Transvaal Hydraulic Power Syndicate obtained a licence from the Transvaal Government for the erection of the power station and the grant of a definite area of supply. The scheme was a large one, involving the expenditure of about £1,000,000 and the arrangements in connection with it were of an onerous character. These arrangements were, however, proceeding, and they believed that ere long they would be definitely concluded. While the arrangement between the companies could not be other than a good one for the Hydraulic Syndicate, inasmuch as they would obtain their coal at a price which did not obtain in Europe, it would be satisfactory to the colliery company, not only on account of the profit that might arise from it directly, but also from the increased profit on their general trade through the spreading of their costs over so greatly enhanced an output. A not unimportant factor in connection with this contract was that they only mined a limited width of the 20 ft. seam of coal on the property. Under their contract at least half the amount to be supplied to the Hydraulic Syndicate was to be taken from the remaining portion of the seam—that was the portion now left in the mine. The quantity of such coal already developed by the operations of the last three years to Dec. 31 last was no less than 1,043,391 tons, which of itself would enable them to supply the Hydraulic Syndicate for some years. The contract being for a long period, the directors thought it right to have an estimate made of the tonnage contents of coal on the property. Taking the main seam alone, the quantity was estimated at 34,000,000 tons, and that by itself would enable them to maintain their present output to the general trade and meet their contract with the Hydraulic Syndicate for over 60 years. Beyond that they had seams of coal both above and below the main seam which were not taken into calculation. They were now prepared not only to fulfil the contract for the supply of the large tonnage referred to, but they looked forward to the supply of a greatly increased tonnage from the expansion which they believed must inevitably take place in the demand of power from the new power station.

United States.—A chain hoist operated by a 150 H.P. electric motor is being fitted at the shipyard of Booz Bros., Baltimore, for hauling vessels up on to a marine railway. It is anticipated that a vessel of 2,000 tons will be hauled out in 30 minutes.

On the steamer "Pilot," belonging to the Maryland Pilots' Association, lying off the Virginia capes, has been placed aloft an electric light which is used for signalling to an observing station at Cape Henry, by the Morse system, the name of any vessel passing in or out of Chesapeake Bay. The system has proved very successful.

The construction of the Susquehanna river dam at McCall's ferry, which ceased in 1908 owing to financial difficulties, was resumed in 1909 after the works and undertaking had been sold by auction for $2,000,000 to the Pennsylvania Water & Power Co., and the work was completed in September last. The company have erected a power house containing 10 large water wheels and two dynamos of about 10,000 kw. each. The contract for the supply of electricity made by the original company with the Consolidated Gas, Electric Light & Power Co. of Baltimore, has been carried out by the present company, and supply was commenced on Oct. 14, 1910. The Baltimore Co. controls the lighting by electricity from this source of eight counties in Maryland. The United Railways Co., with whom the original promoters of the water conservation scheme also had a contract, have not yet taken a supply of current.

The chief engineer of the Sewage Commission proposes, as soon as the sewage disposal plant at Back River—the point of the final discharge of the sewage into the Chesapeake Bay—is completed, to use the fall of the water after it has passed through the various tanks, which will be 18 ft., to operate turbines for the generation of electricity. It is expected that about 455 H.P. will be obtained. The intention is to light and provide current for power at the disposal works, and the chief engineer believes that the surplus will be sufficient to light the City Hall and Court House in Baltimore.

The construction of underground conduits for electric wires at Baltimore goes rapidly forward. There had been constructed to Dec. 1, 1910, 9,463,650 duct feet, which, with manholes, junction and service bases, buildings connected, &c., cost £526,755. The rentals received for the use of the conduits average £20,576 a year. The police and fire-alarm telegraph occupies 103,000 ft. of the conduits, and there are several thousand feet occupied by the municipal and Government cables, for which no rental is received.

An electric iron smelter on the Pitt River, Shasta County (Cal.), has been pronounced a success, and five more furnaces are in course of construction. The cost of production is said to average £2. 10s. per ton, and the product can be sold for £6. 5s. per ton. The pig iron produced is of high quality.

An aqueduct is being constructed to bring the waters of the Owens river to Los Angeles, the main object being to supply water to the city, but the use of the water power for generating electrical energy is also contemplated. It is expected that sufficient power for factories employing 500,000 workers will be obtained, the estimated maximum power obtainable being 120,000 H.P.

The total mileage of electric tramways in the city of Los Angeles is reported to be 350 miles, and on the suburban electric railways over 770 miles of track.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Bolton.—The accounts of the electricity department for the year to March last show capital expenditure £380,611 (increase £20,921), of which £117,501 has been repaid.

The income was £70,942 (£73,579 in 1910), working expenses £35,554 (£38,637), and gross profit £35,388 (£34,941). After providing for interest and instalment for repayment of loans, setting aside £3,504 (£4,664) for renewals, contributing £2,980 (£13,780) to capital, and placing £113 (nil) to reserve, £6,500 (as in previous year) has been voted in aid of rates, and £357 (£619) carried forward. Works costs were 0·456d. (0·436d.) per unit, and total costs 0·570d. (0·535d.), or 1·173d.

Digitized by Google

(1·125d.) including capital charges. The increase in the cost per unit is mainly due to the decrease in the power demand (4,904,527 units compared with 6,013,928),and of the power consumers who have ceased taking current some had a good load factor. The total quantity generated was 13,753,232 (14,257,251), and the total sold 11,156,084 (11,993,271) units. There are 2,851 (2,628) consumers, with 456,986 (434,561) (equivalent) 8 c.p. lamps connected, and the motors connected are 1,029 (915), with an aggregate of 10,584 (10,017) H.P. The average price obtained was 1·23d. (1·18d.) per unit.

Brighton.—The total revenue of the tramways department for the year ended March 31 was £50,747 and working expenses were £37,669.

Out of the gross profit of £13,078 interest absorbed £7,918 and sinking fund £5,023, leaving a net profit of £137. Power expenses were £10,116, against £10,903, traffic expenses £13,253 (£13,119), repairs and renewals £10,386 (£9,249) and management and general expenses £3,007 (£2,889). Car-miles run were 1,126,676 (1,130,685), and the number of units of electricity used 2,023,109 (1·79 per car-mile) (1,938,305) 1·71 per car-mile. The number of passengers were 10,708,184 compared with 10,759,947. In his report the manager (Mr. Marsh) states that the cost of repairs and renewals to permanent way had been increasing somewhat rapidly of late, and the maximum had not been reached. The cost during last year was £5,554 against £4,005.

Coventry.—The report of the electricity department for the year ended March 31 states that the net surplus is £16,414, against £10,070 in 1909-10.

It is proposed to devote £3,500 to relief of rates, and the employés of the department are to get £237 as bonus. It has also been decided to increase the salary of the manager (Mr. G. Tough) from £450 to £550 per annum. The report and accounts were adopted by the Council on Wednesday, when meter rents were reduced and a revised scale of charges adopted.

Dundee.—The accounts of the electricity department for the past year show a total revenue of £46,047, compared with £39,908 for 1909-10.

The generating cost was £13,595; distribution, £2,919; rents, rates and taxes, £4,640; and administration, £1,816. The net profit was £22,957 and the balance brought forward £1,259. The present capital debt is £241,885. The number of units sold during the year was 7,720,018, against 6,144,957.

Hastings.—The income of the electricity department for the year ended March was £18,398, including £13,296 from the sale of current (at average price of 5·385d. per unit), £3,677 from public lighting, £690 interest and sinking fund charges upon loans chargeable to Public Lighting Committee and £679 meter rental.

The total expenditure was £9,138, including £5,293 for generation, £735 for distribution, £819 for public lamp maintenance, £471 rent, rates and taxes, £1,492 management and £328 special charges. The gross profit was £9,260, and after providing interest (£5,167), loans and sinking funds (£5,711) and bad debts (£59) there was a deficit of £1,677, against £2,919. The outstanding debt is £113,840. 915,097 units were generated, against 846,546, and 812,397 units were sold, against 731,914. There are 115 arcs and 320 incandescent lamps, against 115 and 1,357 respectively in 1910. The total maximum supply demanded was 580 kw. (530 kw.); there are 1,153 (1,067) consumers, with the equivalent of 40,697 (39,823) 30-watt lamps connected. The load factor was 15·98 (15·76) per cent. The total costs were 2·44d. (2·86d.) per unit, and coal and other fuel cost 0·86d. (1·06d.).

Kettering.—The accounts of the electric lighting department for the year ended March show total receipts £10,140, including £7,124 nett from sale of current for private lighting, £877 from public lighting and £1,420 from rental of motors, meters and arc lamps.

Total expenditure was £4,912, and included £2,718 for generation, £744 for distribution, £254 for public-lamp maintenance, £137 for rent, rates and taxes, £812 for management and £246 special charges. Gross profit was £5,228, and after paying interest (£1,751), instalments of money borrowed (£2,477) and taking into account £444 brought forward, the balance carried forward was £1,476. The existing debt is £46,270, against £47,747; 1,048,314 units were generated; 917,952 were sold to private consumers and 1,100 by contract and 62,042 units were supplied to the public lamps (30 arc lamps combined with 60 incandescents, 229 half-night and 19 all-night lamps.) The total maximum supply demanded was 624 kw.

South Shields.—The annual report of the tramways manager (Mr. L. E. Harvey) for the year ended March 31 has been issued.

Traffic revenue was £29,046 (8·627d. per car-mile), and after paying expenses (including interest and sinking fund) there was a profit of £2,344, an increase of £693 compared with 1909-10. The improvement is due almost entirely to economies effected in the current bill. Working expenses (£18,493) were practically the same as last year, except for the saving in cost of power and the increase in permanent way expenses. The number of units consumed was 914,046, from which had to be deducted 11,026 sold to power consumers, 1,310 used by the watering car and 2,654 used in the workshop, leaving 899,056 units for traction purposes. In the previous year the figure was 1,070,343, the total saving in traction current being 171,319 (or 16 per cent.). The cost of current for the past 12 months was £5,367. 14s. 5d., an average of 1·411d. per unit, and the cost of the units used for traction was £5,282. 11s. 8d., a reduction of £906. 11s. 7d. The number of miles run was 808,062·12, an average of 1·113 units per car-mile used, against 1·326, a reduction of 16·06 per cent. Those results were due to use of meters on the cars, which had taught the drivers to economise in the use of the current. The operating costs for the year were the fifth lowest in the kingdom, exclusive of costs for power, over which the tramway undertaking had no control. The number of passengers carried was 9·01 per car-mile, against 9·94 for the whole of the kingdom. Owing to the reduced consumption, the average price per unit had increased to 1·409d., against 1·388d. Passengers carried was 7,275,818. The capital expenditure is £172,255. 1s. 6d.

West Hartlepool.—The accounts of the electricity department show capital expenditure £92,548 (increase £457), of which £31,770 has been repaid or placed to credit of sinking fund or reserve.

Revenue during the year to March last was £15,974 (against £15,538 in previous year): working expenses £8,506 (£8,650), gross profit £7,468 (£6,888), and net surplus, after providing for capital charges, £1,506 (£1,128). This has been carried to reserve. Fuel cost 0·39d. per unit sold (against 0·41d. in previous year), works costs were 0·73d. (0·75d.), and total costs 0·88d. (0·94d.), or 1·54d. (1·61d.) including capital charges. Average prices obtained were 1·62d. (1·67d.) for private supply and 1·86d. (1·57d.) for public lighting. The maximum supply demanded was 1,088 kw. (1,070 kw.). 2,496,142 (2,387,222) units were generated, 2,113,558 (1,998,508) supplied to private consumers by meter and 60,329 (59,686) to public lamps.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1911 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 24th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1911 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

The Secretary of H.M. OFFICE OF WORKS invites tenders for providing and erecting at the South Kensington generating station complete surface-condensing plant, capable of dealing with 15,000 lb. of steam per hour, together with the necessary gantry and stanchions. Forms of tender and further information may be obtained at H.M. Office of Works, Engineering Division, 55, Whitehall, London, S.W., and tenders addressed to the Secretary must be delivered by 11 a.m. of Friday, June 30, at Storey's Gate, London, S.W. See also an advertisement.

The Commissioners of H.M. WORKS AND PUBLIC BUILDINGS also invite tenders for the supply of hemp and steel wire lift ropes during three years from July 1. Forms of tender, conditions of contract, &c., from the Storekeeper, H.M. Office of Works Stores, 12, Lambeth-Palace-road, London, S.E. Tenders by 11 a.m. of Monday, June 12, to the Secretary, H.M. Office of Works, Storey's Gate, London, S.W. See also an advertisement.

KETTERING Urban District Council invite tenders for the supply, delivery and erection at their electricity generating station of extension pipework, oil eliminating plant, &c. Copies of specification and general conditions of contract from the Clerk of the Council, Mr. John Bond, Council Offices, Kettering, where tenders must be delivered by June 19. Specifications, general conditions and drawings can be seen at, but not obtained from, the offices of the consulting engineers, Messrs. Kennedy & Jenkin, 17, Victoria-street, Westminster, S.W. See also an advertisement.

Digitized by Google

Tenders are invited up to July 19 for the supply of insulators, telephones, copper and iron wire to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W. See an advertisement.

The Council of the Metropolitan Borough of POPLAR invite tenders for supply, delivery and erection of one 3,000 kw. turbine alternator, complete with surface condensing plant; two water-tube boilers with superheaters, air heaters, fans and chimneys; one 30-ton electric overhead travelling crane and water softening plant. Specification and form of tender from the borough electrical engineer and manager (Mr. J. Horace Bowden), Glaucus-street, Bromley-by-Bow, E. Tenders to the town clerk (Mr. L. Potts), Council Offices, High-street, Poplar, London, E., by 10 a.m. Monday, June 19.

OLDHAM Corporation Electricity Committee invite tenders for the supply, erection and delivery of one 1,200 kw. mixed-pressure steam turbine, coupled direct to two d.c. generators in tandem, together with barometric condenser, pumps, &c. Copies of specification, general conditions, &c., from the borough electrical engineer, Mr. S. Wilmott Newington, Greenhill, Oldham.

STEPNEY (London) Borough Council invite tenders for 12 months' supply of ampere-hour meters, demand indicators and time switches and arc-lamp carbons. Specifications, general conditions and forms of tender from the borough electrical engineer and manager (Mr. W. C. P. Tapper). Tenders to 27, Osborn-street, London, E., by noon June 8.

BARNES Council require tenders by noon June 9 for supply of pilework, 600 kw. generator panel and 1 mile of three-core, paper-insulated lead-sheathed and steel-armoured cable. Specification, &c., from the engineer.

DEVONPORT Electricity Committee want tenders by noon June 8 for 12 months' supply of d.c. meters, paper-insulated cables and rubber-covered wires. Forms of tender, &c., from the Borough Electrical Engineer.

SWINDON Corporation require tenders by noon June 20 for the supply and erection of a 220-cell battery, an automatic reversible traction booster, a three-wire hand-regulated booster, and switchgear. Specifications, &c., from the Borough Electrical Engineer.

STEPNEY (London) Council require tenders by noon June 15 for the constructional steel work of a sub-station at Wapping. Form of tender, &c., from the Borough Engineer.

SWANSEA Corporation require tenders by noon June 13 for the supply of c.c. motors and starting switches. Forms of tender, &c., from the Borough Electrical Engineer.

BELFAST Asylum Committee require tenders by noon June 12 for the electric lighting of two villas at Purdysburn. Specifications, &c., from the Town Clerk.

BECKENHAM Council want tenders by 4 p.m. June 12 for the wiring of houses. Forms of tender, &c., from the engineer, Electricity Works, Beckenham.

HESTON and ISLEWORTH Council require tenders by noon June 14 for supply of metallic filament lamps for street lighting. Particulars from the Engineer, Electricity Works, Hounslow.

WORTHING Corporation require tenders by noon June 12 for supply and erection of two Diesel oil engines and c.c. generators, sub-station, &c., from the Borough Electrical Engineer.

STRETFORD Council want tenders by June 10 for supply of booster booster set. Specification, &c., from the Electrical Engineer.

STOCKPORT Electricity and Tramways Committees require tenders by noon June 14 for supply of overhead material, ironmongery, insulators, paints, waste, &c. Forms of tender from the Engineer.

LONDON County Council require tenders by 11 a.m. July 4 for four electric traversers for car-sheds. Specification, &c., from the Clerk.

Tenders are invited up to July 25 for the supply of 12 sections for switching multiple magneto lamp signalling switchboard, &c., for automatic or semi-automatic switchboard, &c., and up to for supply of 1,400 protectors for use on main distributing of magneto exchanges to the Postmaster-General's Department, Victoria, Tender forms, &c., from 72, Victoria-street, London, S.W.

The Town Clerk, WANGANUI, N.Z., will receive tenders until July 12 for of generating plant, gas-producing plant and battery and for the Corporation tramways. Specification can be seen at Broughall-street, London, E.C. Local representation is necessary.

The American State Railways Department, LEMBURG, will receive tenders to June 15 for supply of electric carbons, &c.

CALARSHI (Roumania) municipal authorities invite tenders for a 35 years' concession for electricity supply in Calarshi. Provisional deposit of £480 will be required with tenders.

The Chairman of the Board of Control, WINNIPEG (Canada), will receive tenders until 11 a.m. July 3 for supply and installation of a police patrol telegraph system.

NAPLES Municipal Authorities require tenders by July 9 for supply and installation of the following plant in connection with the supply of electric power to Naples from the river Volturno:

1. Tubing and accessories for harnessing the water at rate of 7,000 litres a second and for the fall of 190 meters; upset price 702,900 lire (£28,116.)

2. Machinery and apparatus for hydro-electric power station, transmission line (about 57 miles), and transforming station; upset price 1,000,000 lire (£40,000.)

Tenders to Presidente del Consiglio Generale dell' Ente Autonomo Volturno, Naples.

Manufacturers who are prepared to supply 600 km. (372 miles) copper wire 8 mm. dia. are invited to communicate with the Direzione dell' Ente Autonomo Volturno, Naples, who after two months from April 10 will send invitations to tender to firms whom they consider suitable.

Conditions of tender, &c. (*in* Italian) may be seen at 73, Basinghall-street, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

St. Pancras (London) Council received the following tenders for supply of a 1,000 kw. generator to King's-road generating station:—

Bruce Peebles & Co. (*accepted*) **£2,500.** Crompton & Co. £2,236, Siemens Bros. Dynamo Works £2,240, British Westinghouse Co. £2,232, £2,390 and £3,163, Brush Co. £2,625, Electric Construction Co. £2,775, General Electric Co. £2,896, Dick, Kerr & Co. £3,140, J. H. Holmes & Co. £3,150, British Thomson-Houston Co. £3,191, Lancashire Dynamo and Motor Co. £3,207. 10s., Vickers Limited £3,754, Ernest Scott & Mountain £3,845, Rees Roturbo Mfg. Co. £4,020.

The electrical engineer (Mr. S. W. Baynes), in a report on the tenders, stated that the two best offers were those of Bruce Peebles & Co. and the second alternative of the British Westinghouse Co. Although the efficiencies of the British Westinghouse rotary would represent a saving in cost of running so far as coal consumption was concerned, the Bruce Peebles set would require fewer auxiliaries, and would consequently be less expensive to maintain, and would also be easier to manipulate. In comparing the cash prices of the two offers, extras to the switchgear to the value of £180 would have to be provided by the Council in the case of the British Westinghouse Co.'s offer, so that the two tenders would work out as follows: Bruce Peebles & Co. £2,500, British Westinghouse Co. £2,570

St. Pancras (London) Council have received the following tenders for supply of high-tension cables:—

Western Electric Co. (*accepted*) **£904. 2s.**, Standard Cable Co. £829. 19s., Aubert, Grenier & Co. £891, Johnson & Phillips £919. 12s., W. T. Henley's Co. £925, Siemens Bros. & Co. £933, British Insulated & Helsby Cables £941. 12s., Union Cable Co. £950. 19s., Felten & Guilleaume Carlswerke £955, W. T. Glover & Co. £957, Callender's Co. £968, General Electric Co. £1,053. 8s. 4d.

The Electricity and Public Lighting Committee, reporting on the tenders, stated that the works of the two lowest-mentioned tenders are situated abroad, and if either of the offers were accepted it would involve loss of time and expense for the electrical engineer to attend and test the cable before delivery.

St. Pancras (London) Council have also accepted the tender of the Albion Clay Co. for supply of stoneware ducts, at £297. 1s. 5d.

On Tuesday the London County Council were recommended to accept the tender of Walter Scott (Ltd.) for tramway rails at £9,700.

Some particulars of the other tenders received appeared in our issue of May 19 (page 232), and Mr. H. Ward moved that the recommendation be referred back so that the question of the acceptance of the lowest tender (for German rails) should be taken into consideration. He said that although half a dozen English firms were invited to tender, only one submitted a tender. After discussion the amendment was defeated and the Committee's recommendation adopted.

Hammersmith (London) Council have accepted the following tenders:—

Dorman, Long & Co., foundations for new turbo-generator, £36.0s.8d.; Ferranti (Ltd.), equipment of turbo-panel, £180; Pontifex & Co., street lanterns for metal filament lamps, £268. 15s.; British Thomson-Houston Co., "Tirrel" regulator, £105.

Ilford Council have accepted the tender of the Union Cable Co. for foreign-made cable at £1,304. There were seven tenders for British and four for foreign-made cable, and the lowest tender for British-made cable was stated to be £400 higher than the amount of the accepted tender.

Margate Council has accepted the tender of Kingston & Co. for wiring the new pavilion at £729. 15s. (There were 24 tenders, varying from £729. 15s. to £1,250.) The Council also has accepted the tender of Stuart & Moore for fire alarms at £32. 15s.

Kingston-on-Thames Council have accepted the tender of Siemens Bros. & Co. for 880 yd. 0·1 sq. in. l.t. cable at £185; and that of the Craigpark Electric Cable Co. for 440 yd. of 0·05 sq. in. h.t. cable at £73. 2s. 6d.

The D.P. Battery Co. (Ltd.), of Bakewell, have secured the contract for the new storage battery at Aldershot.

Bristol Docks Committee have accepted the following tenders:—Railway & General Eng. Co., permanent way requirements; Johnson & Phillips, cables and wiring for new sheds at Royal Edward Dock; J. H. Tucker & Co., main switchboard, &c.; Simplex Conduits (Ltd.), conduits.

Rochdale Tramways Committee have accepted the tender of the J. G. Brill Co. for 10 pairs of tramcar trucks; that of the British Westinghouse Co. for magnetic brakes; and that of the Brush Co. for car bodies.

Stoke-on-Trent Council have accepted the tender of Siemens Bros. Dynamo Works for two 600 kw. motor generators at £2,385; and that of Callender's Co. for mains and feeders at £14,185.

Hull Electricity Committee have accepted the tender of J. T. Levitt (at £10,999) for extensions of the electricity station buildings and that of G. H. Panton & Son £799) for sub-station.

Bolton Tramways Committee have placed an order with E. Dewhurst for automatic tramway signals.

Barnstaple Council have accepted the tender of H. R. Williams & Co. for wiring the Rock Park bandstand at £29.

Blackpool Council have placed an order with J. W. Fielding & Co. for wiring the new Carnegie library.

Eccles Council have accepted the tender of Matthews & Yates for three cyclone electric fans for the Town Hall, with wiring, at £63.

Maidstone Council have placed an order with the Bambridge Patent Flexible Shaft Co. for a rail grinder at £54. 11s. 6d.

Barking Council have accepted the tender of A. E. Synes for the erection of extensions to the electricity station buildings, at £2,497.

Mixed-Pressure Turbine.—Queensland Railway Commissioners have placed an order with Willans & Robinson, of Rugby, for a 750kw Willans impulse-disc and drum turbine, with a General Electric Co.'s two-phase alternator and surface-condensing plant. The turbine will be capable of giving its normal full load with high-pressure steam or with any mixture of high-pressure and exhaust steam, and is intended for the Ipswich locomotive works of the Government railways.

Government Contracts.—The following tenders were accepted by British Government Departments during April:—

Admiralty.—Evered & Co., Gabriel & Co., General Electric Co., Ingram & Kemp, Sir J. Laing & Sons, W. McGeoch & Co. and Player & Mitchell, brackets, pendants, &c.; British Insulated & Helsby Cables, Edison & Swan Co., Evered & Co., India Rubber, Gutta Percha & Telegraph Works Co., W. McGeoch & Co., Sterling Telephone & Electric Co., Veritys Limited, A. Watson & Co. and Westminster Engineering Co., switches, sockets, &c.

War Office.—Tudor Accumulator Co., storage batteries; Brotherton Tubes & Conduits, Eureka Conduit & Fittings Co., Nettlefold & Sons, Perfecta Seamless Steel Tube & Conduits Co. and Simplex Conduits, conduit fittings.

India Office.—D.P. Battery Co., accumulators; British Insulated & Helsby Cables, cable; India Rubber, Gutta Percha & Telegraph Works Co., cable core, &c.; Veritys Limited, fans; Bullers Limited & Taylor, Tunnicliff & Co., insulators; British Westinghouse Co., motor, &c.

Crown Agents for the Colonies.—General Electric Co., electrical materials.

Office of Works.—J. C. Christie, electric bellhangers' work.

General Post Office.—Western Electric Co., telephone apparatus; Houghton's Limited, battery boxes; British Insulated & Helsby Cables and Johnson & Phillips, paper-core cables; Western Electric Co., s. & c. core cable; Siemens Bros. & Co. and Telegraph Construction & Maintenance Co., submarine cable; J. R. Crompton & Bros., tinfoiled condenser paper; J. C. Fuller & Son, flameproof wire; W. J. Furse & Co., electric lighting of new money order office, Holloway, London; British Insulated & Helsby Cables, local telephone exchange equipment at Wimbledon; Marconi's Wireless Telegraph Co., wireless telegraph power plant for Crookhaven.

BUSINESS NOTICES.

Messrs. W. T. Glover & Co. ask us to state that, owing to the resignation of Mr. Scott, of Glasgow, who has represented them for many years, they have appointed Mr. McEwan (who has for a considerable period represented them in the East of Scotland) as their sole resident representative for the whole of Scotland. They will continue to carry large stocks of rubber-insulated cables at Glasgow (196, St. Vincent-street) and Edinburgh (9, Clyde-street).

Walter Trevelyan Wright and Jas. Miller (trading as the Electric and Automatic Engineering Co. and the New Enterprise Co.), George-street and 1, Watts-place, Chatham, have dissolved partnership. Debts by Mr. Wright.

Geo. Bradwell, the younger, and Matt Jennison, electrical engineers, formerly of 4, St. Ann's-square, Manchester, and 77, Victoria-street South, Grimsby, have dissolved partnership. Debts by Mr. Jennison.

The Globe Electric Co. have taken up the manufacture of signs and have acquired additional space at 11, Farringdon-avenue, London, E.C.

General Electric and Westinghouse Interests.—It is announced that, as from April 30, the agreement relating to overlapping patents entered into in 1896 between the General Electric Co. of New York and the Westinghouse Electric & Mfg. Co. of America has expired, and, being considered no longer necessary, will not be renewed.

Sale by Auction.—By order of the receiver (Mr. G. E. Corfield) of the Ferabin Lamp and Electrical Accessories Co. (Ltd.), Mr. Frank G. Bowen will sell by auction on the premises, 41, New-street Mews, Dorset-square, London, W., on Wednesday, June 14, at 1 o'clock, the extensive stock, plant and machinery of electrical accessory manufacturers, including 3,000 battery cases, pendants, brackets and lanterns, glass shades and globes, electric bells and pushes, wire, casings, electric fittings, switches, lamps, lamp-carriers, eight electric motors, seven drilling machines, tools, &c. On view day prior to sale. Catalogues of Messrs. Corfield & Cripwell, Balfour House, Finsbury-pavement, London, E.C., on the premises; and of the Auctioneers, 62A, Aldersgate-street, London, E.C. See advertisement.

BANKRUPTCIES, LIQUIDATIONS, &c.

The first meeting of creditors of John D. Carlmark, electrical engineer, West Bromwich, was held at Birmingham on Friday.

The statement of affairs showed liabilities expected to rank £442.19s.6d. assets estimated £51. 15s. 6d., deficiency £391. 4s. Debtor began business without capital as an electrical engineer and electro-plater in 1899 partnership, which traded at first as the West Bromwich Electric Light & Power Co., and later as Richardson & Carlmark. No balance-sheets or profit and loss accounts were ever prepared beyond rough estimates, which were not retained. The partnership was dissolved in May, 1910, there being at that date a deficiency of assets to meet the firm's liabilities of about £280. Debtor had also private liabilities amounting to £80. The matter was left with the O.R.

A dividend is to be paid to creditors of A. C. A. Wampach, electrical engineer, Formby Lodge, Seabrook-road, Hythe. Claims to Mr. J. O. Morris, 68A, Castle-street, Canterbury, by June 10.

A meeting will be held at 10, Walbrook, London, E.C., on June 26 to receive an account of the winding-up of the Brockie-Pell Arc Lamp (Ltd.)

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked* are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

April 5, 1911.

8,446 ELEV. Batteries.
8,460 BARTON & CARTER. Earthing device.
8,484 MARTYN. Bonding devices for electric cables and electric fittings. (Divide application on 9,921/10. April 23.)
8,489 BARDOUR. Control of alternating-current electric motors.
8,515 JOHNSON. Switches.
8,524 MACKU. Arrangement for producing slightly damped electric oscillations. (Convention date, 2/5/10, Austria.)*
8,530 STEVENS. Means for economically charging batteries from a supply at constant potential.

April 6, 1911.

8,585 CHIGER. Time switches.
8,589 CARRICK & GREENWOOD & BATLEY. Direct-current machines.
8,591 SIEMENS BROS. DYNAMO WORKS & LYDALL. Speed control of electric motors.
8,592 SIEMENS BROS. DYNAMO WORKS & KLOSS. Starting of alternating-current electric motors.

April 7, 1911.

8,656 ENGISCH. Brush for electric engines.
8,665 BARRON. Electrical toasting and like heating apparatus.
8,688 ROBINS & WALFORD-GROUT. Method of providing temporary auxiliary electric current in case of failure or partial failure of the main source of supply, and apparatus and appliances connected therewith.
8,710 WERNER. Sparking plugs.
8,712 GES. FUR DRAHTLOSE TELEGRAPHIE M.B.H. Arrangement for producing slightly damped electric oscillations. (Convention date, 2/11/10, Austria.)*
8,720 PECHIN. Rotary electric contacts.*

April 8, 1911.

8,767 DRUSEIDT. Switches. (Addition to 9,399/10.)*
8,783 LEWIS. Control systems for alternating-current electric motors. (Convention date, 9/4/10, United States.)*
8,798 BRULL. Electrically controlled grab hoisting gear. (Convention date, 10/10/10, Germany.)*
8,806 LODGE & ROBINSON. Wireless telegraphy.

April 10, 1911.

8,846 THOMSON. Hand and belt electric lamps.
8,853 TAYLOR. Changing the frequency of alternating-current systems.
8,890 DAVEY & CO. & TOWLER. Controlling gear for or connected with electrical driven hydraulic pumps.*
8,899 NICHOLSON & BROOKING. Electrically-controlled valves.
8,943 WOODS. Driving of alternating-current motors.

April 11, 1911.

8,951 STEEL, PEECH & TOZER & BOWEN. Electric magnetic lifting-appliances used with cranes. (Addition to 30,075/10.)
8,978 GOLDSCHMIDT. Intensifying of weak alternating currents. (Convention date, 11/4/10, Germany.)*

[illegible] Brenner. Arrangement for electrically transmitting compass positions to a distance. (31/3/10.)

COMPANIES' MEETINGS AND REPORTS.

ANGLO PORTUGUESE TELEPHONE CO. (LTD.)—At the meeting on [illegible]day Mr. H. Allen said that was the fourth time in succession they had paid 5 per cent. dividend with a closed capital account and a very [illegible] year's business. Having regard to the general position of affairs in Portugal it behoved them at the present time to keep their eyes on their [illegible] reserves. In their last 10 years their gross income had increased from £29,223 to £54,391; their gross profit from £4,967 to £21,614, and their net profit from £3,519 to £17,330. Their income in the last 10 years had increased nearly 200 per cent. and their profit nearly 500 per cent., while in the last five years their income had increased about 80 per cent. and their profit about the same. If they were given a little more latitude and some concession in the management of their business in Portugal, they could do even better. They had in common with other employers had in Portugal one or two strikes to trouble them. At Oporto in particular it looked at one time as if they should have serious trouble. Thanks, however, to the courageous and firm handling of the situation by their local manager (Mr. Street) the strike was effectually stamped out and the business in Oporto was now working normally. At Lisbon, he was glad to understand, they had been rather more fortunate than some other employers of labour. They were carrying a larger sum to reserve (£10,000 against £7,500), but they carried forward about £500 less.

PANBURY & DISTRICT ELECTRIC SUPPLY CO. (LTD.)—It was reported at the meeting last week that the total capital expenditure at Dec. 31 was £20,052. 12s. 5d. The year's revenue was £3,075. 15s. 10d., and after deducting expenditure (£1,968. 16s. 8d.) and adding balance forward brought forward £1,113. 1s. 2d. The directors recommend a dividend of [illegible] per cent. on the ordinary shares. The demand for electrical energy for lighting and power continues to increase, the equivalent of 20,867 lamps being connected, against 18,173 8 c.p. in 1909.

BIRMINGHAM & MIDLAND TRAMWAYS (LTD.)—The total revenue for the year was £102,018, compared with £99,713 for 1909. The expenses were £53,293, against £48,710. After providing for all expenses chargeable to revenue, including repairs, maintenance, sums payable to corporations and £5,000 to renewals, there remains £45,915, added to £149 brought forward, making £46,064. Deducting interest on loans (£6,812) and interest on debenture stock (£15,178) the balance was £24,072. After deducting £4,228 for debenture sinking fund and the preference dividend there remains £8,306. The directors recommend a dividend of 3 per cent. on the preferred ordinary shares (£7,000), in placing £1,000 to renewals and reserve, and to carry forward £306. The gross receipts from tramways were £48,025, against £46,477; and gross receipts from electrical power £26,737, increase £6,942. The capital expenditure during 1910 was £31,017 (£444 on tramways and £30,573 on lighting). At the meeting on Wednesday the Chairman (Mr. C. S. B. Hilton) said they had made distinct progress and were able to recommend a slightly increased dividend. They had now turned the corner, and they looked forward to the future with a certain amount of confidence. The loan from the Shropshire Power Co. remained practically at the same figure, and the directors had decided to write down the investment in the Motor Omnibus Co. The traction section during the past four years had, in spite of all drawbacks, shown steady if somewhat slow growth, while the lighting section had more than justified the hopes he expressed last year, and shows largely-increased gross receipts and a satisfactory ratio of expenses. The electric light section had also increased from £8,303 to £26,737. The expenses of both sections had decreased, and the position generally showed good progress. That those improved results were not reflected in improved dividends to the extent they should like was chiefly due to the lower returns on their investments in other companies. He had to announce with much regret that their general manager (Mr. Cramp) had retired. He has been with the company for over 16 years, and during that period he had rendered valuable and ungrudging service to the company. They had parted with him with very great regret, but they had been fortunate in obtaining the services of Mr. W. G. Bond to replace him. Mr. Bond, until he took the position, was one of the directors, and therefore well known to them all. He had a knowledge of the business and an interest in it, and he was in every way qualified to succeed Mr. Cramp.

BRUSH ELECTRICAL ENGINEERING CO. (LTD.)—The directors' report for 1910 shows gross profit £28,200, but debiting general charges and maintenance, and debenture and other interest, there is an adverse balance of £10,800. The amount now standing to debit of profit and loss account (£61,100) and the fact that depreciation not yet provided for has taken place in certain of the company's investments point to the necessity of an early re-organisation of the share capital.

CALLENDER'S CABLE & CONSTRUCTION CO. (LTD.)—The accounts for 1910 show a balance of £55,838. 11s. 10d., making, with £42,202. 9s. 10d. from 1909, £98,041. 1s. 8d. Deducting debenture interest (£13,500), preference dividend (£10,000) and depreciation of buildings, plant and machinery (£8,217. 12s. 7d.), the available balance is £66,323. An ordinary dividend of 10 per cent. (less tax) or 10s. per share (5s. paid in November) requires £17,500, and a bonus of 5s. per share (less tax) £8,750, carrying forward £40,073. 9s. 1d.

DEVONPORT & DISTRICT TRAMWAYS CO.—During 1910 £79. 14s. 5d. was expended on capital account, making the total £162,467. 14s. 11d. The total revenue for the year was £22,902. 1s. 1d., an increase of £3,155. 18s. over 1909, but expenses increased £1,401. 14s. 2d. Deducting all expenses, the surplus is £571. 17s. 11d., which is carried forward. The increase in receipts and expenses is partly due to the fact that the company is again working the lines leased from Devonport Corporation. The inspector appointed by the Board of Trade to test the meters measuring the energy purchased from the Corporation reported in November last that the meters were reading fast and ordered certain adjustments. Meters have been fixed on all the company's cars, and as a result of the more careful driving there is a substantial reduction in the amount of electrical energy consumed.

HONG KONG ELECTRIC CO. (LTD.)—At the recent meeting, Mr. J. W. C. Bonnar said the result of the past year's working had been satisfactory, showing a balance of $177,716·10, compared with $169,595·48. In view of the increased use of metal filament lamps and of the rebates given to large consumers that result must be gratifying to them. That had led the directors to consider the advisability of purchasing another Diesel engine to meet the increasing demand for current, and they expected shortly to place an order for a larger engine than those at the station. They proposed to pay a dividend of 12 per cent. and a bonus of 1 per cent. The sum set aside for depreciation was large, but it was necessary. The efficiency of the company depended largely on their keeping up to date.

JOHNSON & PHILLIPS (LTD.)—Mr. Robt. W. Blackwell, presiding at the meeting last week, said the balance-sheet marked a distinct advance over the position to which the company was brought by the bad business of several succeeding years. They suggested that a considerable sum should be written off for depreciations during the present year, owing to the fact that during the period of their greatest depression, some three years ago, some question arose as to whether they had properly and sufficiently seen to those items. As to the general business of the company, he thought they could fairly say that the corner had been well and safely turned, and if the conditions of business in the country continued as seemed likely, he thought Johnson & Phillips could look forward to a substantial business year by year. During the whole time of the depression nothing had been neglected to strengthen the position of the company's works. They had done everything that was required to maintain them, to throw out old machinery and to bring in new and better materials, and their shops and works in general were in a better condition to-day than they had been since be became connected with the board. In their cable works, and in the shops where they made machinery for the manufacture of cables, they had been practically full all the year round, and the turnover of the business had only been exceeded once during its existence as a company. The amount of business in hand at present was very large. They had in hand in the works in uncompleted orders a sum of £77,508, which was some £30,000 more than they had in the same month last year. He referred with regret to the death of Mr. Bonner, and announced that Sir Henry Benbow, who had also been a member of the board since the registration of the company, had resigned.

Mr. Thos. Dence, who seconded the motion for the adoption of the report and accounts, said that the company enjoyed a splendid reputation, equal, for the quality of their manufactures, to that of any of their competitors. They had amongst their customers practically all depart-

Digitized by Google

ments of the British Government and many foreign Governments, as well as British and foreign railways, electric lighting companies and other first-class companies and firms, from whom they received regular orders, and amongst whom their reputation stood unquestioned. During the first three months of the present year the amount of business done constituted a record, and they had at present sufficient orders and contracts in hand to keep the various manufacturing departments employed for the next six months. They should have further working capital to enable them to carry out to the best advantage the numerous orders and contracts on hand, but they were unable to raise it by any fresh issue of stock which would have to rank behind their debentures. Therefore they used the net profit to strengthen their financial position. Had the average annual profits of Johnson & Phillips (Ltd.) during the first few years of the company's history been equal to the last years of the firm from whom they purchased, the burden could have been borne without serious detriment, but, unfortunately, there came a period of depression in the electrical trade, and their company had felt the effects most severely.

KALGOORLIE ELECTRIC POWER & LIGHTING CORPN. (LTD.)—At the meeting on Wednesday the chairman (Mr. R. W. Wallace, K.C.) said that during the past year there had been one or two drawbacks. There had been a fire at the Great Boulder Perseverance Co.'s mine. That company was their principal customer, and owing to the fire the supply of electricity to the mine was stopped. Nevertheless, they had succeeded in increasing their revenue, and that was largely due to the board's policy of putting down new plant and maintaining the old plant from the first in an efficient condition. The new unit was working satisfactorily, and now that the Great Boulder Perseverance mine was being operated again they were supplying a larger load than during any previous month. For April last their profit was double that for the corresponding month of 1910, and their prospects for the current year were extremely good.

LEWES & DISTRICT ELECTRIC SUPPLY CO. (LTD.)—Capital expenditure during 1910 was £314. 18s. 10d., making, with £31,054. 15s. 8d. previously expended, a total of £31,369. 14s. 6d. Revenue amounted to £2,633. 9s. (an increase of £231. 5s. 7d. over 1909), and all expenses to £2,030. 9s. 1d., leaving £602. 19s. 11d. The demand for electrical energy for lighting and power continues to increase steadily, and the equivalent of 15,457 8 c.p. was connected, against 14,116 8 c.p. in 1909.

POTTERIES ELECTRIC TRACTION CO. (LTD.)—At the meeting on Monday Mr. G. F. M. Cornwallis-West said that the net result of the year's working was that they had increased their profits by £164 compared with 1909. Traffic receipts increased £418, parcels receipts £250, advertising receipts £23, sundry receipts £451, and interest on their holding in the North Staffordshire Tramways Co. £1,156. The total increase in receipts was £2,298. They had carried 524,162 fewer passengers, but had received a slightly higher fare per passenger (1·24d. against 1·2d.) The "fair fare" system was not a success from the point of view either of the public or of the company. They ran 29,800 miles more than last year. Repairs and maintenance increased by £1,690, over 81,000 of which was accounted for by the increased expenditure on permanent way.

RIO DE JANEIRO TRAMWAYS, LIGHT & POWER CO. (LTD).—The gross earnings of the company's tramway, electric light and power, gas and telephone undertakings in April were £211,667 (increase £42,098). The aggregate from Jan. 1 was £809,356 (increase £155,765).

URBAN ELECTRIC SUPPLY CO. (LTD.)—At the meeting on Wednesday Mr. P. D. Tuckett said that in a year in which few electric supply undertakings had shown any marked increase in profits there was no occasion to be dissatisfied with an increase of £2,403. The profits earned by the various undertakings amounted to £47,253, against £44,849, and the net balance was £44,911. During the year, instead of the estimated output of 5,800,000 units at 5½d. per unit, they had sold less than half that number for private lighting, whilst the 6,100,000 units which they had sold for power only realised an average of 1·07d. per unit. With regard to the tramway load, they would have been better off without it.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES, &c,

NEW COMPANIES.

A. L. P. SYND. (LTD.) (116,021.)—Reg. May 25, capital £20,000 in £1 shares (10,000 preference), to construct, maintain and work tramways and railways in Buenos Aires and La Plata. Private company.

ASSOCIATED FIRE ALARMS (LTD.) (116,004.)—Reg. May 24, capital £160,000 in 60,000 preference shares of £1 each and 400,009 ordinary shares of 5s. each, to carry on the business of manufacturers of fire indicators, extinguishers, escapes and engines, and other implements and machinery, &c., and to acquire and amalgamate the undertakings of the Pearson Fire Alarm (Ltd.) and the May-Oatway Fire Appliances (Ltd.) First directors, G. H. Brown, J. Heal, E. W. Elliott, H. C. Hall, A. Hair and A. D. Fairbairn. Reg. office, Jewin House, Redcross-street, London, E.C.

ELECTRO-FLEX STEEL CO. (LTD.) (115,987.)—Reg. May 23, capital £25,000 in £1 shares, to acquire any inventions relating to electric furnaces, the electrical smelting of ores and the refining of metals or to electric batteries, electro-chemical or electro-thermal processes, &c. Private company. Reg. office, 86, Collingwood Buildings, Collingwood-street, Newcastle-on-Tyne.

ENGINEERING & ARC LAMPS (LTD.) (116,030.)—Reg. May 25, capital £3,000 in £1 shares, to take over the arc lamp manufacturing and engineering businesses carried on at Chingford and St. Albans, together with certain rights and properties connected therewith, and to adopt agreements with the Gilbert Arc Lamp Co. (Ltd.) and J. S. Hecht. Private company. First directors, J. S. Hecht (chairman), C. E. Gilbert and W. J. Davy.

JAMES J. GUEST & CO. (LTD.) (115,993.)—Reg. May 23, capital £20,000 in £1 shares, to adopt an agreement with J. J. Guest for the acquisition of the business of a mechanical and electrical engineer and manufacturer of grinding machines. Private company.

PATENT SERIES LIGHTING CO. (LTD.) (115,997.)—Reg. May 23, capital £5,000 in £1 shares, to carry on the business of an electric light company, &c. Private company. First directors, E Booth and N. R. Booth.

TELEPHONE DISINFECTING CO. (LTD.) (116,001.)—Reg. May 23, capital £2,000 in 1,980 ordinary shares of £1 each and 400 deferred shares of 1s. each, to carry on the business indicated by the title. Private company. First directors, C. E. Evans and A. E. Withers. Reg. offices Finsbury Chambers, Finsbury-pavement, London, E.C.

STATUTORY RETURN.

METROPOLITAN ELECTRIC SUPPLY) CO. (LTD.)—In the return to March 28 capital is £1,500,000 in £5 shares (100,000 preference). 200,000 ordinary and 76,121 preference shares taken up. £5 per share called up on 195,936 ordinary and 76,121 preference. £1,360,285 paid, £20,320 considered as paid on 4,064 shares. Mortgages and charges, £498,000.

MORTGAGES AND CHARGES.

DAVIS ELECTRICAL CO. (LTD.)—Particulars of £2,000 debentures, created May 16, have been filed, amount of present issue being £1,100. Property charged, company's undertaking and property, present and future, including uncalled capital (subject to £2,000 first mortgage debentures). No trustees.

ENGLISH ELECTRICAL CO. (LTD.)—Issue on May 11 of £1,000 debentures, part of a series of which particulars have been filed.

CITY NOTES.

MEMORANDA (June 1).—**Bank rate 3 per cent. (March 9, 1911). Price of silver, 24 ⅝d. per oz. Consols 81⅛—81⅛ for money and 81⅛—81⅜ for account. Consols Pay Day, July 3; Stock and Shares Continuation Days, June 13 and 28; Ticket Days, June 14 and 29; Pay Days June 15 and 30; Mining Shares Carry Over Day, June 12.**

PRICES OF METALS (London).—*Copper*, cash, 55⅞; three months 55⅛. *Lead*, English, 13⅜—13⅝; foreign, 13⅛—13⅜. *Spelter*, 24⅛—24⅜. *Tin*, English, 196½—197½; foreign, 210 cash, 190 three months. *Iron*, Cleveland, cash, 46/5, three months, 47/2.

ADELAIDE ELECTRIC SUPPLY CO. (LTD.)—The directors have declared an interim dividend of 3s. 6d. per share, less tax, on the ordinary shares.

CALCUTTA ELECTRIC SUPPLY CORPN. (LTD.)—The number of units delivered to consumers during the five weeks ended March 31 were 801,705 compared with 743,651 units in the corresponding period of 1910. For the four weeks to April 28 the units were 787,233, against 780,51 in 1910.

COMPANIES TO BE STRUCK OFF THE REGISTER.—The following will b struck off the Register of Joint Stock Companies unless cause is shown t the contrary before Aug. 30:—

Amalgamated Dry Batteries, Edison-Gower Bell Telephone Co. (reg Sept. 1, 1898), Elmore's American and Canadian Patent Copper Deposit ing Co. Elmore's Foreign and Colonial Patent Copper Depositing Co Elmore's Patent Copper Depositing Co., Elmore's Wire Mfg. Co., South Western Electrical Co.

MACKAY COMPANIES.—The regular quarterly dividends of 1 per cent on the preferred and of 1¼ per cent. on the common shares in the Macka Companies will be paid on July 1 to shareholders of record as they appe at the close of business June 10. The transfer books will not be closed.

METROPOLITAN RAILWAY CO.—Mr. F. McLaren, M.P., has bee elected a director in succession to the late Sir Wm. Birt.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee hav appointed June 15 a special settling day in and have granted a quotatio to a further issue of £600,000 5 per cent. 50-year mortgage bonds of th *Rio de Janeiro Tramway, Light & Power Co.*, and have granted quotation to a further issue of £50,000 4½ per cent. debenture stock of the *County London Electric Supply Co. (Ltd.)*, $1,847,000 additional consolidate mortgage 5 per cent. 50-year coupon bonds of 1952 of the *Havana Electr Railway Co.*, and a further issue of £27,000 4½ per cent. first mortga prior lien gold bonds of the *Montreal Water & Power Co.* The com mittee have been asked to appoint a special settling day in, and granted quotation to £61,400 4¼ per cent. debentures, 1934, of the *Christchur Tramway Board*, and also to allow a further issue of £205,480 4½ per cen perpetual consolidated mortgage debenture stock of the *Shawinig Water & Power Co.* to be quoted.

WESTERN TELEGRAPH CO. (LTD.)—The directors have declared th third quarterly interim dividend of 3s. per share (tax free) for th year ending 30th inst., being at rate of 6 per cent. per annum. Th transfer books will be closed from June 14 to 20 inclusive, and t dividend will be payable on June 21.

NOTES.

A Lesson from Bolton.

A POWER load is always liable to show considerable fluctuations from year to year owing to the varying condition of manufacturing industries, but fortunately it is not often that such a serious decrease has to be recorded as that experienced by the Bolton electricity department during the past year. The accounts of this department for the year ended March 31st last, which were abstracted in our last issue, show that owing to several large power consumers, representing a load of 1,500 kw., no longer taking a supply from the undertaking, the output for power had decreased by over 1,000,000 units, or 18·4 per cent. The loss of these consumers has been due to the Electricity Committee being unwilling, in spite of a favourable report by the engineer, to offer a supply at a sufficiently low rate. In view of the success that has attended Mr. A. A. DAY's efforts in the past to develop cheap power supply, it is to be regretted that the diminished output on the present occasion has resulted in a check to the reduction in the working expenses which it has been our pleasure to chronicle from year to year. As, however, the department quickly weathered a slight set-back two years ago, due to trade depression and strikes, we hope that the present check will be as rapidly surmounted. A satisfactory portent in this direction is that the number of motors connected to the mains has increased during the past 12 months by 114, equivalent to 567 H.P.

ALTHOUGH the loss of the large power consumers at Bolton is unfortunate, it may, nevertheless, serve a useful purpose by drawing attention to the fact that "cheap power supply" is by no means unprofitable to the supply authority, as is sometimes stated to be the case. The reduction in the output at Bolton is largely of low-priced units, as is evident from the fact that the average price per unit received for motive power has increased from 0·812d. a year ago to 0·896d. in the present accounts, and it has resulted in the total cost per unit (excluding capital charges) increasing from 0·535d. to 0·570d., and in the profit shown on the year's working falling from £7,119 to £6,857. The effect, however, is much greater than is shown by the last-mentioned figures, since they include the profit on the fittings department. This profit was £2,829 as against £1,163 in the previous year, so that the profit on the supply undertaking has really decreased by £1,928. It has, nevertheless, been decided to allocate £6,500 to the relief of the rates, a similar contribution to that made in the two preceding years.

American Telephony and the Post Office.

FROM the "Daily Mail" we learn that a party of engineers on the staff of the British General Post Office recently paid a visit to the U.S.A. to investigate the development of American telephony and that a report giving the results of this investigation has been printed for circulation among the heads of departments. We do not question the desirability of such a course; but as to the details of the investigation we are unable to say very much, because it appears that the report is not available—at least to the technical press. The "Daily Mail," however, is evidently in a more favoured position, and publishes an interview with one of the officials concerned, who gives some account of the

Digitized by Google

more important telephonic differences between this country and the United States, as embodied in the report. To most people this will seem an unusual procedure. If information was to be given to the public we should have expected it to be given by the Engineer-in-chief, though perhaps the present method is in keeping with the desire for publicity sometimes evident in other branches of the public service. Further, we should have expected information of this kind to be given to the technical press rather than to any one of our daily contemporaries, for such matters are essentially within the province of the technical journal.

Turning to the few technical details which are given, it appears that the telephone service in America is more flexible than in this country, in that any telephone exchange can be used as a sort of bureau of general information. The local service is also somewhat quicker, which is purely a matter of training the staff, as the equipment is the same. Trunk services are also quicker; this seems to be due to the fact that trunk lines have been laid down on a much more lavish scale, and consequently the tariff for long distance messages is much higher than in this country. To most subscribers here this will, doubtless, appear a disadvantage which more than counterbalances the speed of obtaining the desired connection. Finally, the British Post Office engineers appear to have been very favourably impressed by the automatic telephone exchanges. There is no question that working by means of automatic instruments can be more rapid than manual working, as any delay on the part of the operator is avoided. This, however, is not the only point to be taken into consideration, as became apparent in the recent discussion at the Institution of Electrical Engineers. Perhaps the semi-automatic method of handling telephonic traffic, as described in another column, may meet the conditions in this country better than automatic working pure and simple. In any case there seems to be no question that the automatic telephone now demands serious consideration.

Progress at Last.

The selfish attitude of a number of local authorities towards applications for provisional electric lighting orders in the early days of electricity supply retarded the normal development of the industry in many towns. In some cases the municipalities prevented companies from coming in and establishing electricity undertakings, and in not a few instances where Local Authorities obtained provisional orders no attempts were made to carry out the provisions of the orders. During the last year or two, however, the Board of Trade has shown increased vigilance in regard to the intentions of applicants for powers to supply electricity, and many of the long outstanding orders have been revoked. The case of Macclesfield is typical of many, and the fact that this town of about 35,000 inhabitants is still unprovided with a supply of electricity illustrates the backward state of the industry in this country. The Corporation obtained an electric lighting order so long ago as 1901, but as no undertaking had been established the Board of Trade revoked the order last year. Unable themselves to supply the ratepayers with electrical energy, the Corporation recently refused their consent to the granting of an order to a company. As the Corporation did not assign any reasons for their objections, it is satisfactory to note that the Board has decided to dispense with the consent of the Corporation, and to grant the order. The position, however, is somewhat complicated by the fact that a Bill of the Macclesfield & District Rail-less Electric Traction & Electricity Supply Co. is also before Parliament, and the question as to which of these companies shall obtain powers to supply electrical energy in the borough will be considered by a Select Committee of the House of Lords at the end of this month.

Illumination Risks.

The popularity of the phrase "It is supposed that the fire was caused by the fusing of an electric wire" shows no signs of waning, and in this respect the enterprise and originality of the British journalist is seriously open to question, though possibly the explanation is that compositors have instructions to insert this time-honoured sentence in all accounts of fires. We have suspicions that lack of "copy" owing to the Whitsuntide holidays is responsible for the prominence that has been given to several fires during the last few days and to their supposed electrical origin. A drapery establishment, premises occupied by licensed victuallers and a "joy wheel" are all involved but the grounds on which blame is attached to the electri circuits are, as usual, not stated. A member of the sta of the youngest of London's evening dailies has been inte viewing a Fire Brigade official as to possible dangers fro Coronation illuminations, and has learnt that "in mos cases the fusing of wires is almost impossible to prevent. This is news indeed! The fact that the regulations issu by the Corporation of London as to illuminations on refer to electrical apparatus, perhaps implies that they e pect electrical devices alone to be in evidence, as at prese seems probable; but in any case it is desirable to emphas the necessity of running no risks of electric lamps comi into contact with inflammable decorations. That fires more likely to originate in that manner than from defecti circuits is undoubtedly the case, and it is noteworthy th the Fire Brigade official referred to above, mentioned Japanese lamp as a possible cause of the recent fire at Edinburgh Empire Music Hall. We would suggest to daily contemporaries the use of some such alternat during the next few weeks.

Concrete Pole Construction in Oklahoma.—According the "Electric Railway Journal," one of the inter-urban lin the Oklahoma Railway is equipped with reinforced conc centre poles with semi-ornamental pipe brackets. This i experimental equipment of 20 poles installed late in 1 These poles are of the hexagonal type, 30 ft. high with tops and reinforced walls 3½in. thick. The manufactu cost per pole was 34s.

Personal.—We offer our congratulations to Sir Oliver Lodge on his 60th birthday, which we understand will be celebrated on the 12th inst.

University of Oxford.—In Convocation, on June 20th, it is proposed to confer the honorary degree of Doctor of Science on Prof. T. W. Richards, of Harvard University.

Steel for Magnets.—According to the "Electrical Review and Western Electrician," an alloy containing 8 per cent. of molybdenum, 0·3 of 1 per cent. of vanadium and 0·6 of 1 per cent. of carbon makes good permanent magnets, which retain their magnetism up to a temperature above 1,000°C. Four per cent. of tungsten with 0·4 of 1 per cent. of vanadium has also been found to be a good combination.

Electric Propulsion for Ships.—Trial runs took place last week of the new experimental boat, the "Electric Arc," which has been equipped by Messrs. Mavor & Coulson with electrical transmission between the prime mover and the propeller shaft. The most interesting feature of the vessel, perhaps, is that alternating-current plant is employed, the system being that of Mr. H. A. Mavor. The ease with which stopping, starting, speed-changing and reversing can be carried out was demonstrated and the trials proved very satisfactory.

"The Self-Discharge of Planté and Faure Storage Batteries."—In a Paper on this subject read before the American Electrochemical Society by Messrs. O. W. Brown and W. G. Rowe, the authors gave some data showing that the Planté type of cell loses its charge when allowed to remain on open circuit for periods of 10 to 20 days. The Faure cell, when made from pure materials, suffered only very slight loss in capacity when left on open circuit. In every test the self-discharge of the Faure cell was much less than in cells of the Planté type. The data also showed that the Planté cell suffered permanent injury when considerable periods of time were allowed to elapse between the charges, while one or two re-charges of a Faure cell restored it to its original capacity. In the light of these results, the Faure type of cell was, the authors considered, best suited for all service where intervals of a week to a month or more must elapse between charges. This condition was found in some telephone plants, in isolated lighting plants, and these cells were used for ignition purposes and for the operation of signal systems.

Macclesfield Electric Lighting Order, 1911.—The Board of Trade have made a special report under sec. 1 of the Electric Lighting Act, 1888, on the application of the New Electricity Co. of Macclesfield for a provisional order to supply electricity in Macclesfield.

Macclesfield Corporation refused their consent to the order and lodged objections without assigning any reasons for their objections. The Corporation themselves obtained an electric lighting order in respect of the borough in 1901, but as they failed to establish an undertaking, the Board of Trade revoked the order in 1910. The order applied for this year was also opposed by the promoters of the Macclesfield and District Rail-less Electric Traction and Electricity Supply Bill now before Parliament. Under this Bill powers are sought to establish a system of electric traction in the borough and certain adjoining districts, and to supply electricity for public and private purposes in Macclesfield. The Board invited representatives of the promoters of the provisional order and the objectors to attend at the office of the Board to discuss the matter, and after carefully considering all the circumstances, the Board decided to dispense with the consent of the Corporation and to grant the order, leaving to Parliament the question of determining whether powers for the supply of electricity within the borough of Macclesfield should be vested in the promoters of the order or in the promoters of the Macclesfield and District Rail-less Electric Traction and Electricity Supply Bill.

Mr. Marconi on Wireless Telegraphy.—In the course of a lecture delivered at the Royal Institution on Friday evening last Mr. Marconi made a number of interesting statements regarding the present position of wireless telegraphy. He stated that the arrangement at Clifden which gave the best results was based substantially on his syntonic system of 1900. Air condensers were now used, greatly reducing the loss of energy which took place by dielectric hysteresis. In his opinion it was neither economical nor efficient when utilising the best receivers to make the waves too continuous. Much better results were obtained when groups of waves were emitted at regular intervals in such a manner that their cumulative effect produced a clear musical note in the receiver, which was tuned not only to the frequency of the electric waves transmitted, but also to their group frequency. The lecturer also dealt with the employment of direct current, the propagation of waves during daylight and the importance of the earth connection. The concluding part of the lecture was devoted to a consideration of the distance over which wireless messages could be transmitted. Over the sea a distance of 4,000 miles had been covered, and Mr. Marconi did not think he was too bold in saying that wireless telegraphy was tending to revolutionise our means of communication.

We hope to deal further with this interesting lecture when the full report is available.

Constantinople Telephone System.—Messrs. F. Gill and W. W. Cook, engineer-in-chief and assistant engineer-in-chief of the National Telephone Co., have been appointed consulting engineers to the Constantinople telephone scheme, the formal agreement for which was executed between Djavid Bey, then Minister of Finance, and Mr. Herbert Laws Webb, at Constantinople on May 6. We are informed that a staff of engineers left London last week to make a telephonic survey of Constantinople and to prepare plans and specifications for the system, which is to have an original capacity of 10,000 lines and to be ready to start service in July, 1913. Mr. John Scott is in charge of the engineering force, and left London last week for Constantinople.

The work Mr. Scott has in hand is one of many difficulties, as Constantinople is the most peculiarly situated of all European capitals. The city is divided by the Bosphorus, which is deep and has swift and variable currents, and, moreover, is much used as an anchorage. The European section is again divided by the Golden Horn, an arm of the sea over which there is no permanent bridge. In all parts of the city the streets are extremely primitive, narrow, winding and ill-paved, and many of them are precipitous hills. As no telephone service yet exists in Turkey, all modern facilities having been debarred by the ex-Sultan, there are no available data whereby to gauge the probable use of the service or the probable traffic which the system will be called upon to carry. The peculiar composition of the population of Constantinople, about one-half of which consists of non-Moslem races, Greek, Armenian, Jewish and so on, makes the business part of the engineering problem one of much complexity. Three languages are current—Turkish, Greek and French—while many more are spoken, and the variety of local customs and practices is probably greater than in any other large city in the world. No exact statistics exist, but the population of the area is estimated at between 1,000,000 and 1,250,000 inhabitants. Means of communication are at present so primitive and expensive that a large demand for the telephone service may be anticipated. The Telephone Development Co. (Ltd.) has been formed for the purpose of carrying on the necessary work pending the organisation of the Ottoman Telephone Co., which will construct the plant and operate the service.

Annual Tables of Constants and Numerical Data.—At the International Congress of Applied Chemistry held in London in 1909 an International Commission was appointed for the purpose of compiling and publishing annual tables of constants and numerical data. This Commission was subsequently accorded the patronage of the Association of Academies at the meeting of that body held in Rome in 1910. According to the programme drawn up by the Commission the tables published in any one year are intended to contain all the numerical data likely to be of interest in connection with chemistry, physics and allied sciences, pure and applied, which have found a place in the literature published during the previous year. The data are to be accompanied by full bibliographic references. This programme has now so far matured that portions of the volume for 1910 are, we understand, already in the press, while the manuscript of the remaining portions is approaching completion. Owing to the immense volume of scientific and technical literature which is continually being produced, the difficulties in the way of finding out whether any given measurement has been made or not are increasing year by year. Existing systems of indexing and abstracting are only a limited help, since a large number of measurements are made in the course of researches to which they are purely subsidiary, so that their existence cannot be inferred from the titles and sub-titles of the Papers in which they are recorded. Also tables which appear only at long intervals, such as those of Landolt and Börnstein, can of necessity cover only a small part of the ground; and,

Digitized by Google

moreover, in most cases they are hampered by the limitations of private enterprise. The annual tables should, therefore, the compilers feel, fill a serious gap which has hitherto existed in the systematic indexing of scientific and technical results. It is hoped that the enterprise may ultimately become self-supporting; but, obviously, this cannot be the case for some time to come. The Commission has been greatly assisted by grants from various societies—for example, in this country from the British Association, Chemical Society, Faraday Society, Royal Dublin Society, Royal Irish Academy, Royal Society of Edinburgh, and the Society of Chemical Industry. Donations have also been received from a few private persons, notably from the Right Hon. the Earl of Berkeley, F.R.S. The financial position, however, is still far from satisfactory, and further help from societies and private donors is urgently needed. In this connection it may be mentioned that neither the general secretary, nor the members of the Commission receive payment for their services, except in so far as they may perform actual compiling or abstracting. The organisation of the Commission is sufficiently complete to deal effectively with periodical literature, but it happens occasionally that data are published only in non-periodical publications, such as books or monographs; and such data may easily be overlooked. Accordingly, in order that the annual tables may be as complete as possible, the authors of such books, monographs, &c., are requested to communicate with one or other of the members of the Commission. In cases where the data are numerous, specimen copies or corrected proofs of the tables containing the data would be very acceptable. The members of the International Commission for the United Kingdom are: Dr. Alex. Findlay (The University, Edgbaston, Birmingham); Dr. R. T. Glazebrook, C.B., F.R.S. (The National Physical Laboratory, Teddington, Middlesex); and Dr. N. T. M. Wilsmore (University College, Gower-street, London, W.C.). The general secretary is Dr. Charles Marie (98, Rue du Cherche-Midi, Paris, VI.).

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Dr. R. Beattie contributes an article on "Harmonic Analysis Diagrams."

Mr. C. C. Hawkins contributes an article on "The Principle of the Static Balancer."

We give an abstract of a Paper by Mr. P. Longmuir on "The Corrosion of Metals," read at the recent meeting of the Iron and Steel Institute. The subject of corrosion is also discussed in our Leading Article.

At a recent meeting of the American Institute of Electrical Engineers, Mr. E. E. Clement read a Paper on "The Semi-automatic Method of Handling Telephone Traffic."

Messrs. G. J. Hooghwinkel and F. Thursfield contributed a Paper to the Staffordshire Iron and Steel Institute on "The Electric Driving of Light Rolling Mills."

The first annual conference of the Electric Supply Publicity Committee was held last week in London, when an interesting discussion took place on methods of advertising electricity supply undertakings.

In a recent report the Postmaster-General gave particulars of the progress made with the work of laying underground telegraph cables throughout the kingdom.

Legal.—On Tuesday Lord Ormidale commenced the hearing of the action by Johannesburg Municipal Council against D. Stewart & Co., 1902 (Ltd.) and their guarantors for, *inter alia*, damages for alleged breach of contract in connection with the supply of gas producer plant for the electricity department of the Council.

Companies' Meetings and Reports.—The directors' report of the Victoria Falls & Transvaal Power Co. gives particulars of the progress during 1910. Arrangements have been made to issue further debentures to the amount of £1,300,000.

The report of the directors of the British Electric Traction Co. gives particulars of the progress made during the year by the various undertakings in which the Company is interested.

At the meeting of Callender's Cable & Construction Co. yesterday (Thursday), the managing director (Mr. Tom O. Callender) gave interesting particulars of the past year's trade and particularly of the development of the foreign department.

OBITUARY.

J. W. Boucher.—We regret to record the death of Mr. Jas. W. Boucher, Dublin branch manager of the Edison & Swan United Electric Light Co., which occurred on the 2nd inst. Deceased, who had been in ill-health for some time, was found dead in his office with a bullet-wound through his forehead and a six-chambered revolver in his right hand.

Baron d'Erlanger.—In our issue of June 2nd (p. 235) we published a statement that the death had occurred of the chairman of the General Traction Co., Baron E. B. d'Erlanger. This is not the case, the deceased gentleman being Baron Frederic Emile d'Erlanger, father of Baron E. B. d'Erlanger.

PERSONAL NOTE.

We regret to have to announce that Prof. D. Capper, of King's College, London, has sustained a serious accident. He was riding in Rotten Row, Hyde Park, London, on Tuesday morning when his horse fell and he was thrown heavily upon his head. He was taken to St. George's Hospital in an unconscious condition, but recovered consciousness in the course of the day. He has sustained a fractured skull, but the latest news of his condition is satisfactory.

APPOINTMENTS VACANT AND FILLED.

Sunderland Corporation require a superintendent to take charge of mains and sub-stations on power, lighting and traction systems, and operating upon the three-phase and c.c. systems. Salary £182 per annum. Applications to the engineer and manager, Mr. Alfred Blackman, M.I.M.E., M.I.E.E., Electricity Offices, Dunning-street, Sunderland. See advertisement.

A first class mechanical and electrical engineer is required, with thorough experience in modern manufacture of c.c. and a.c. machinery. See advertisement.

A demonstrator in physics is required for Armstrong College Newcastle-on-Tyne. Salary £100 rising to £120. Applications to Mr. F. H. Pruen, secretary, by June 23.

Mr. Jas. A. Wishart, mains superintendent at Motherwell Corporation electricity works, has been appointed electrical engineer to the burgh of Motherwell, at a commencing salary of £250 per annum.

Mr. W. C. Bexon, of Croydon electricity works, has been appointed mains assistant engineer at Kilmarnock.

Mr. L. W. Ballard, who has recently been engaged with the British Westinghouse Co., has been appointed assistant engineer on the staff of Messrs. May & Hawes, Westminster.

Mr. S. Janson, who was manager of the hire and repair business of S. F. Edge (Ltd.) for some years, has been appointed manager of the Electromobile Co. and of the Hertford-street Motor Hiring Co.

Mr. W. Dundas, senior shift engineer at the Neasden power station of the Metropolitan Railway Co., has been appointed shift engineer at the Stuart-street works, Manchester.

Mr. A. G. Low, late switchboard attendant at Tynemouth Corporation electricity works, has been appointed switchboard attendant at the "Chronicle Office" sub-station, and Mr. H. Lister, shift engineer, Middlesbrough Corporation electricity works, has been appointed shift engineer at the Close power station of the Newcastle & District Electric Lighting Co.

Mr. Chas. Brown, engineer to the North British Railway Co., has been appointed chief engineer to the Great Northern Railway Co. in succession to Mr. Alex. Ross.

INSTITUTIONS AND SOCIETIES.

Tramways and Light Railways Association.—The Papers to be read at the annual congress at Edinburgh on July 13 and 14 are as follows:—"Transfer Fares," by Mr. C. W. Shepherd (general manager, Edinburgh Corporation Tramways); "A Few Reasons why Electric Traction in England remains Stationary," by Mr. G. H. Hooghwinkel; "Notes on Tramway Problems," by Mr. C. V. Mallins (general manager, Liverpool Corporation Tramways); and "Tramways and Light Railways Legislation of the Future," by Alderman W. Ivey (West Ham Tramways Committee).

Digitized by Google

Institution of Civil Engineers.—CONFERENCE ON EDUCATION AND TRAINING OF ENGINEERS.—At the Conference to be held on June 28th and 29th the following discussions will take place: "The extent to which mathematical and scientific subjects should share with other subjects of literate education the attention of schoolboys who intend to enter later the engineering profession," introduced by Dr. J. Gow and Prof. S. P. Thompson; "The question of specialised entrance examinations for university or college courses of study in engineering science with a view to the curricula to be followed, and also of the inclusion in the latter of courses in modern languages," introduced by Prof. A. K. Schwartz; "The requirements of practical training and of scientific study and the apportionment of time to them," introduced by Mr. A. F. Yarrow and members of his staff and Mr. W. H. Allen; "Practical training in workshops or on works of construction, with special reference to training in the engineer's office," introduced by Mr. W. B. Worthington and Mr. H. F. Donaldson; "The value of a university degree in engineering science in relation to professional competence," introduced by Prof. S. M. Dixon and Prof. C. F. Jenkin; "The position and uses of engineering laboratories in relation to education at college," introduced by Prof. W. E. Dalby, Prof. John Goodman and Prof. Bertram Hopkinson; "The relation of engineering employers and colleges from the point of view of the practical training of college students," introduced by Prof. J. E. Petavel and Mr. J. W. Horne: "The relation of practical training to college study; whether or to what extent, before, sandwiched, or after its conclusion," introduced by Prof. Archibald Barr and Prof. Henry Louis; "Workshop training as a preliminary to practical training in other branches of engineering," introduced by Mr. J. A. Brodie, Mr. J. M. Monteith and Prof. J. J. Welch.

Physical Society.—On the occasion of the visit to the National Physical Laboratory on May 26th, all departments of the Laboratory were open for inspection, and a number of special demonstrations were arranged. One of the most interesting was the *Silica Standard Metre Bar*, recently constructed as a primary standard of length. This was shown by Mr. J. E. SEARS and Dr. KAYE. The remarkably low coefficient of expansion of fused silica, and its practical freedom from thermal hysteresis, render it a specially suitable material for the construction of permanent length standards of the highest class. Such standards are always handled by trained and skilled observers, so that its comparative fragility is of small import. It is only recently, however, that sufficient progress has been made in methods of manufacture to render possible the construction of a metre standard in silica. The present bar, the first of its kind, consists of a silica tube into which are fused at its two ends optically worked plane parallel slabs of silica that serve to carry the graduations. The under sides of these slabs are platinised, and the graduations made by cutting through the platinum film with a diamond point. The readings are viewed from above through the thickness of the silica end-slabs, so avoiding any apparent alteration of length which might be caused by the shifting of the cover slips that are used to protect the platinum film. The bar is supported at two points, one of which is formed by a trunnion of silica fused into the tube and the other by a wire etched round it. In this way the conditions of support can be easily reproduced whenever the bar is under examination. The thickness and position of the end-slabs are so arranged that the apparent image of the ruling, when the bar is immersed in water, lies in the neutral axis.

Faraday Society.—At a meeting of the Faraday Society, which will be held on Tuesday next at the Institution of Electrical Engineers, Prof. Ernst Cohen, of Utrecht, will deliver a lecture on "Allotropic Forms of Metals." Prof. T. W. Richards, of Harvard University, will preside.

Röntgen Society.—At the annual general meeting of this society, which was held on Thursday, June 1st, at 20, Hanover-square, the following addition was made to the laws of the society—"The name of the society must not be used for purposes of advertising, and the council will not countenance in the slightest degree any conduct of a member tending to use the membership of the society as a qualification for practice."

Institution of Electrical Engineers.—The annual conversazione will be held at the Natural History Museum, South Kensington, on Thursday, July 6th, at 9 p.m., when Mr. and Mrs. S. Z. de Ferranti will receive the guests.

Institution of Gas Engineers.—The annual general meeting of the Institution will be held at the Glasgow and West of Scotland Technical College, Montrose-street, Glasgow, on Tuesday, Wednesday and Thursday next, June 13 to 15, under the presidency of Mr. Alex. Wilson, engineer and general manager, Glasgow Corporation Gas Department. A number of interesting communications will be presented, including one on "Public Lighting," by Mr. S. B. Langlands, of Glasgow, and on Friday, June 16, a steamer excursion on the Firth of Clyde has been arranged. On Tuesday evening, at 8 p.m. a lecture (with experiments) on "Surface Combustion," will be delivered by Prof. W. A. Bone, F.R.S.

Association of Mining Electrical Engineers, West of Scotland Branch.—The election of the following office bearers for the session 1911-12 is announced: *Branch President*: Mr. Alex. Anderson. *Branch Vice-President*: Mr. Matt. Brown. *Hon. Treasurer*: Mr. D. L. Frew. *Hon. Auditor*: Mr. A. B. Muirhead. *Hon. Secretary*: Mr. D. Martin. *Council*: Messrs. F. Anslow, Wm. Brown, J. R. Benson, R. Robertson, A. Power, W. Cairns, J. B. Thomson, W. H. Telfer, H. A. McGuffie, S. A. Simon, C. W. Holman, and J. C. McCullum. The strength of the branch is now 122, and suitable arrangements are being made by the local council for the annual meeting of the parent association to be held in Glasgow on October 6th and 7th next, among the functions being a reception by the Corporation.

EDUCATIONAL NOTICE.

City and Guilds Technical College.—This college provides a scientific training for students preparing to become electrical and mechanical engineers or chemists and for engineering pupils who desire to supplement their practical training by a two years' course of instruction in the principles of engineering science. The instruction is mainly given in the various laboratories, most of which have been recently re-equipped. The college does not prepare students to pass external examinations, but a certificate of proficiency is awarded by the Institute to students who complete a satisfactory course of instruction. The subjects of the entrance examination are mathematics and English, but the matriculation of any British University is accepted instead. The courses in electrical and mechanical engineering cover a period of two years and those in chemistry three years. There are also arrangements for three year courses in engineering. Particulars at the college, Leonard-street, City-road, London, E.C., or from the City and Guilds of London Institute, Gresham College, Basinghall-street, London, E.C.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, June 9th (to-day).

PHYSICAL SOCIETY.

8 p.m. Meeting at the Imperial College of Science. Agenda: "The Lüders Lines on Mild Steel," by Mr. W. Mason; "Exhibition of a Model illustrating the Passage of a Light Wave through Quartz," by Dr. H. S. Allen; "Tables of Circular and Hyperbolic Functions for Complex Values of the Argument," by Mr. A. Johnstone; "On the Measurement of Contact Differences of Potential," by Prof. A. Anderson and J. G. Bowen; "Exhibition of Gyroscopic Apparatus," by Sir G. Greenhill, F.R.S., and "A New Method of Approximate Harmonic Analysis by Selected Ordinates," by Prof. S. P. Thompson, F.R.S.

ROYAL INSTITUTION.

9 p.m. Meeting at Albemarle-street. Discourse on "Applications of Physical Chemistry to the Doctrine of Immunity," by Prof. Svante Arrhenius.

TUESDAY, June 13th.

FARADAY SOCIETY.

8 p.m. Meeting at the Institution of Electrical Engineers, Victoria Embankment. Lecture on "Allotropic Forms of Metals," by Prof. E. Cohen.

WEDNESDAY, June 14th.

ROYAL METEOROLOGICAL SOCIETY.

4·30 p.m. Meeting at 70, Victoria-street, S.W. Paper on "Investigation of the Electrical State of the Upper Atmosphere," by Dr. W. Makower and Messrs. A. J. Makower, W. M. Gregory and H. Robinson.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued for the current week:—

Monday, June 12th, "A" Company.—Technical Drill, 7 to 9 p.m.
Tuesday, June 13th, "B" Company.—Technical Drill, 7 to 9 p.m.
Wednesday, June 14th.—Gymnastic Classes, 7 to 10 p.m.
Thursday, June 15th, "C" Company.—Technical Drill, 7 to 10 p.m. Recruits' Drill, 7 to 8 p.m.
Friday, June 16th, "D" Company.—Technical Drill, 7 to 10 p.m. Recruits' Drill, 7 to 8 p.m.
Saturday, June 17th.—No parades.

HARMONIC ANALYSIS DIAGRAMS.*

BY R. BEATTIE, D.Sc.

According to Fourier's theorem, if y is any single-valued periodic function of θ, we can always represent y as the sum of a series of sines and cosines of multiples of θ in the form

$$y = A_0 + A_1 \sin\theta + A_2 \sin 2\theta + A_3 \sin 3\theta + \ldots\ldots + B_1 \cos\theta + B_2 \cos 2\theta + B_3 \cos 3\theta + \ldots\ldots \quad (1)$$

where A_0, A_1, A_2..... B_1, B_2.....are constants. The constants A_1, A_2... ..B_1, B_2..... are the coefficients of the so-called harmonic components of the periodic variable or its graph; and the variable or its graph is said to be harmonically analysed once these coefficients have been determined.

By writers on harmonic analysis much attention has at various times been directed to simplifying the labour involved in calculating these sine and cosine coefficients, and to this end many abbreviated arithmetical rules and ingenious graphical constructions have been suggested.† For our present purpose it will suffice to remind the reader of the direct or unshortened arithmetical method which is based on the following considerations:—

In the first place, by taking the average over a whole period of equation (1) as it stands, we have

$$A_0 = \text{average value of } y \quad (2)$$

a result which is obvious if we remember that the average value over a whole period of $\sin p\theta$ or $\cos p\theta$, where p is an integer, is necessarily zero.

Again, to determine the coefficient A_n of the sine component of the nth order, multiply both sides of (1) by $\sin n\theta$ and take the average over a whole period of the resulting equation. Remembering that the average value over a whole period of $\sin p\theta \sin q\theta$ or $\cos p\theta \cos q\theta$ where p and q are integers is zero except when $p = q$, when it is $\frac{1}{2}$, and that the average value over a whole period of $\sin p\theta \cos q\theta$ is always zero, we readily see that

$$A_n = 2 \times \text{average value of } y \sin n\theta \quad (3)$$

Similarly, to determine the coefficient B_n of the nth cosine component, multiply both sides of (1) by $\cos n\theta$ and take the average of the resulting equation as before. We thus get

$$B_n = 2 \times \text{average value of } y \cos n\theta \quad (4)$$

In order to prepare the way for subsequent explanation, let it be supposed for the moment that the actual determination by this process of the harmonic components of a given periodic function is carried out with the help of a diagram consisting of a number of parallel scales, as shown in Fig. 1. The base, K_1K_2, of this diagram is taken to represent a complete period, or 360 deg. in angular measure, and is divided up into a convenient number of equal parts, say, m. Through the centre of each part a vertical line is drawn and on each of these verticals a scale of equal divisions is marked off, the scales being the same for all the verticals and all the scales having their zeros on the base line. The scales extend on both sides of the base line and the divisions are marked positive above and negative below.

In using the diagram one complete period of the y-θ graph to be analysed is first drawn in rectangular co ordinates. This must be done on tracing paper and the wave-length or angular period of the graph made exactly equal to K_1K_2. The tracing paper carrying the curve to be analysed is then placed on the diagram, as shown in Fig. 1, so that the base of the curve coincides with K_1K_2.

To find A_0 read off on the several scales of the diagram the intercepts y_1, y_2, y_3, &c., between the curve and its base. Then by (2)

$$A_0 = \frac{1}{m}(y_1 + y_2 + y_3 + \ldots\ldots) \quad (5)$$

To find A_n read off the intercepts y_1, y_2, y_3, &c., as before, and note at the same time the angular distances θ_1, θ_2, θ_3, &c. of the respective ordinates from K_1. Having done this, form

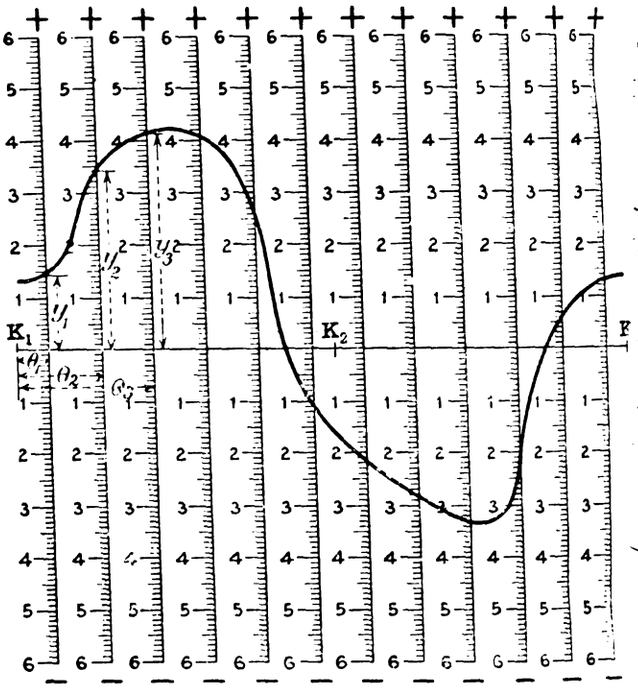

FIG. 1.—DIAGRAM OF UNIFORM SCALES FOR DETERMINING THE CONSTANT TERM IN THE FOURIER SERIES FOR A GIVEN CURVE.

the products $y_1 \sin n\theta_1$, $y_2 \sin n\theta_2$, $y_3 \sin n\theta_3$, &c., add them together and divide by m to get the mean. Introducing this mean into (3) we have

$$A_n = \frac{2}{m}(y_1 \sin n\theta_1 + y_2 \sin n\theta_2 + y_3 \sin n\theta_3 + \ldots\ldots) \quad (6$$

Lastly, to find B_n form the several products $y_1 \cos n\theta_1$, $y_2 \cos n\theta_2$, $y_3 \cos n\theta_3$, &c. Take the mean of these and introduce into (4) which gives

$$B_n = \frac{2}{m}(y_1 \cos n\theta_1 + y_2 \cos n\theta_2 + y_3 \cos n\theta_3 + \ldots\ldots) \quad (7$$

Reciprocal-sine and Reciprocal-cosine Scales.— Apart from inevitable restrictions on the attainable accuracy due to the limited number of ordinates employed, the only objection to the foregoing process is its laboriousness. This arises chiefly from the necessity of performing the various multiplications which are an essential feature of the method. If the necessity for these multiplications could by any means be done away with, and the operations reduced to additions and subtractions the arithmetical method would compare favourably with even the best of the shorter methods that have been proposed.

The suggestion here made is one by which multiplications are entirely avoided by adopting the very obvious expedient of performing them once for all on the respective scales of the diagram of Fig. 1. For this purpose we have but to alter the units of these scales in a suitable manner. Thus, suppose we wish to construct a diagram to enable the coefficient A_n of the nth sine component to be determined. The unit of the first scale would then be made equal to $1/\sin n\theta_1$, that of the second scale equal to $1/\sin n\theta_2$, that of the third scale equal

$1 \cdot \sin n\theta_2$, and so on, the scales lying above the base being marked with the signs (+ or − as the case may be) of $\sin n\theta_1$, $\sin n\theta_2$ $\sin n\theta_3$, &c., and those lying below the base with the opposite signs. Fig. 2 shows a diagram constructed in this manner. It is clear that if we apply the curve to be analysed to this diagram and read off the intercepts y_1', y_2', y_3', &c., due regard being paid to sign, then from the method of constructing the scales $y_1' = y_1 \sin n\theta_1$, $y_2' = y_2 \sin n\theta_2$, $y_3' = y_3 \sin n\theta_3$, &c. Hence from (6)

$$A_n = \frac{2}{m}(y_1' + y_2' + y_3' + \ldots\ldots) \quad . \quad . \quad . \quad . \quad (8)$$

To construct a diagram to determine B_n, the coefficient of the nth cosine component, we have only to make the units of the scales for the first, second, third, &c., ordinates equal to $1 \cos n\theta_1$, $1/\cos n\theta_2$, $1/\cos n\theta_3$, &c., marking them with the corresponding positive or negative signs above the base, and with the opposite signs below. Fig. 3 shows such a diagram. Applying the curve to be analysed to this and reading off the successive intercepts y_1'', y_2'', y_3'', &c., each with its proper sign attached, then $y_1'' = y_1 \cos n\theta$, $y_2'' = y_2 \cos n\theta_2$, $y_3'' = y_3 \cos n\theta_3$, &c. Hence

$$B_n = \frac{2}{m}(y_1'' + y_2'' + y_3'' + \ldots\ldots) \quad . \quad . \quad . \quad . \quad (9)$$

From their method of construction diagrams like Figs. 2 and 3 might be called "diagrams of reciprocal-sine scales," and "diagrams of reciprocal-cosine scales" respectively. As many of these diagrams would be required as there are coefficients to be determined. A "diagram of uniform scales," like Fig. 1, would also be required to enable the constant term A_0 to be found. A set of diagrams of this kind with scales accurately divided and carefully printed would enable any chosen harmonic component within the range of the diagrams to be evaluated in a straightforward manner and with comparatively little labour, the degree of accuracy attainable depending on the number of scales in the diagram. The curve to be analysed would have to be drawn on tracing paper to the right scale in the first instance. By placing it on the appropriate diagram, reading off on the several scales the successive intercepts between the curve and its base, adding these together algebraically and dividing the sum by $m/2$ (half the number of scales in the diagram), the required sine or cosine component for which the diagram is constructed would be obtained at once and with no more trouble than is involved in the measuring up of an indicator diagram.

If the diagrams used for determining the several sine and cosine components of a curve are all constructed on a uniform plan—that is to say, with the same number of scales in each diagram—then the operation of dividing the sum of the intercepts by $m/2$ could usually be dispensed with, since what is required is not, as a rule, the absolute values of the components, but their relative values only. In these circumstances harmonic analysis would be reduced to a mere matter of addition and subtraction. Circumstances requiring the use of diagrams having a larger number of scales than the normal might arise, however, as when a harmonic of extra high order has to be picked out accurately. In such cases, when the diagrams employed do not all have the same number of scales, the operation of dividing by $m/2$ cannot, of course, be omitted.

Figs. 2 and 3 are correctly drawn 12-ordinate diagrams * for determining the 5th sine and cosine components respectively, the unit of a scale situated at a distance θ from the origin being made equal to $\pm 1/\sin 5\theta$ in Fig. 2, and $\pm 1/\cos 5\theta$ in Fig. 3. In other words, the units of the first, second, third, &c., scales are made numerically equal to $1/\sin(5 \times 15°)$, $1/\sin(5 \times 45°)$, $1/\sin(5 \times 75°)$, &c., in Fig. 2, and $1/\cos(5 \times 15°)$, $1/\cos(5 \times 45°)$, $1/\cos(5 \times 75°)$, &c., in Fig. 3. Besides illustrating the character of the scales, these diagrams provide the reader with a means of estimating for himself the time required to compute a given harmonic. In Fig. 2 the successive intercepts between the curve represented and the base are:— +1·40, −2·32, +1·06, +1·04, −1·93, −1·22, +2·18, −2·08, +0·86, +0·54, +0·40, −1·20, the sum of which is −2·27. Dividing this by 6 (half the number of ordinates in the diagram) we get −0·38 as the required sine component. For convenience in adding, the positive and negative intercepts would in practice be set down in two separate columns as they are read off, and the whole process need not occupy more than about 1 minute.

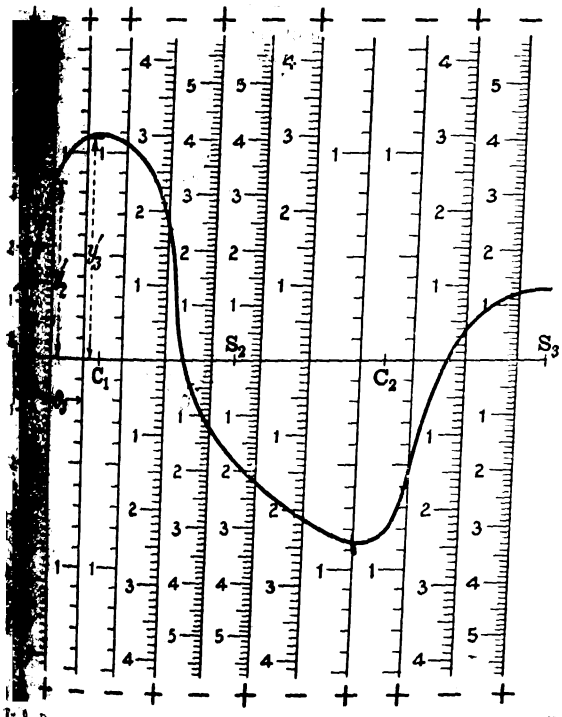

Fig. 2.—Diagram of Reciprocal-Sine Scales for Determining the Coefficient of the Fifth Sine Term.

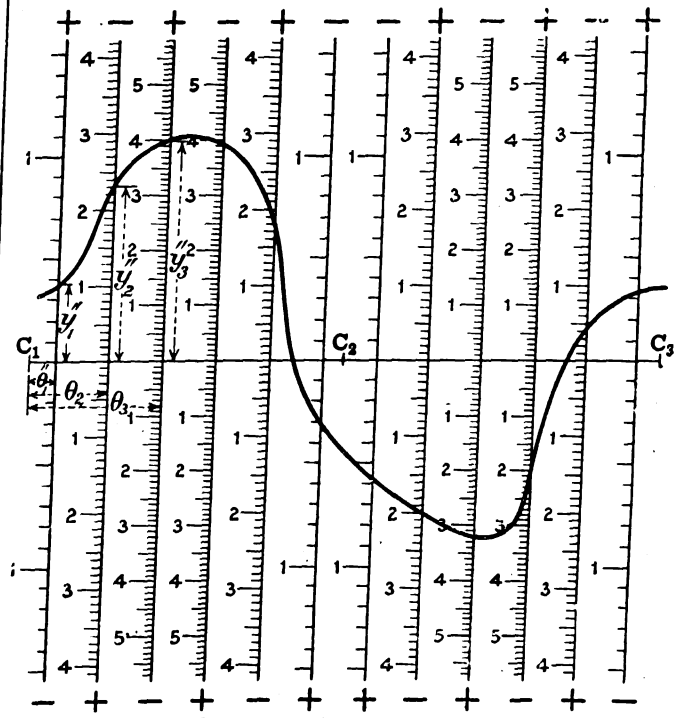

Fig. 3.—Diagram of Reciprocal-Cosine Scales for Determining the Coefficient of the Fifth Cosine Term.

The cosine component, found from Fig. 3 in the same way, is −0·07 and takes an equal space of time to arrive at. If we wish to find the magnitude and phase of the resultant harmonic, we must add a further interval of, say, 1 minute, required to evaluate $\sqrt{(0{\cdot}38)^2 + (0{\cdot}07)^2}$, which is the magnitude, and $\tan^{-1}(-0{\cdot}17/-0{\cdot}38)$, which is the phase, of the resultant. We may therefore put down the total time required to find the magnitude and phase of a single resultant harmonic at, say, 3 minutes. Using 12-ordinate diagrams like Figs. 2 and 3, all the harmonics, both even and odd, up to the sixth order, could thus be determined in about 20 minutes. If diagrams with more than 12 ordinates are used, the time would, of course, have to be increased in proportion.

* These 12-ordinate diagrams are intended for illustrative purposes only; actual diagrams should have at least 24 ordinates, and when greater accuracy is required, or when the higher harmonics are at all prominent, 36 or even 48 ordinates.

When using reciprocal sine scales to analyse alternating-current or other wave-forms which contain odd harmonics only, and in which the second half of the wave is therefore similar to the first, it is unnecessary to employ the whole diagram for a complete wave. In such cases it suffices to take the graph of half the wave to be analysed and place it on the initial half of the diagram—that is, on S_1S_2 (Fig. 2), or C_1C_2 (Fig. 3). The sum of the intercepts divided by half their number still gives, it will be seen, the value of the sine or cosine component for which the diagram is constructed. In certain circumstances the sine diagram can be used for determining the cosine component as well as the sine component. This can be done in the diagram of Fig. 2, for instance, where the part of the diagram lying between C_1 and C_2 is evidently identical with the part of the diagram lying between C_1 and C_2 in Fig. 3. It is only for harmonics of certain orders and for diagrams constructed with a certain number of scales that this holds good, however, and as a general rule it is necessary to employ two separate diagrams, one for the sine component and another and different one for the cosine component.

(*To be concluded.*)

THE CORROSION OF METALS.*

BY P. LONGMUIR, B.MET.

Theories of Corrosion.—The acid theory depends on the presence of oxygen, moisture and an acid, and mere traces of acidity are sufficient to start the reaction. As generally understood, the primary attack is due to carbonic acid, a ferrous salt resulting, which in turn is acted upon by oxygen and water with the formation of rust and the liberation of the acid. In this manner the process is continuous, and a comparatively small amount of acid may exercise a vast influence. The acid theory has been studied in detail by Friend.† Friend also gives an excellent *résumé* of results obtained by other workers in this direction. The electrolytic theory depends upon the solubility of iron in pure water, or, expressed in another form, upon the presence of free hydrogen ions in the purest water. A large amount of experimental work has been done in this direction, and it has been shown that the rusting of iron is principally due to attack by hydrogen ions. Cushman and Walker have respectively presented the case from the electrolytic point of view in two admirable memoirs.‡ Taking the whole of the work done, the balance of evidence appears to be in favour of the electrolytic theory. However, from an ordinary point of view this is of little moment, for the fundamental differences between the acid and electrolytic theories are theoretical rather than practical.

Consideration of Results.—In discussing problems of corrosion it is frequently stated that the examination of corroded residues is inconclusive. So far as chemical constitution is concerned there may be truth in this, but in the majority of cases of exceptional corrosion a detailed examination of the residue will give some clue as to the cause. Results given in the Paper represent instances noted over a long period of time and a diversity of geographical position, yet one characteristic feature is maintained throughout, and that is the distinct content of sulphur in the residues. To some extent corroded deposits may be taken as an index of the sulphurous character of the surrounding atmosphere. In no problem of corrosion can local conditions be ignored, and in most instances they are of equal importance to the character of the metal which has been corroded.

The Real Problem of Corrosion.—The problem of corrosion does not lie in the amount of metal lost by rust or decay, but on the influence exerted on the metal remaining intact and apparently unaffected. Deterioration is found which is not explained by mere loss in weight or by change in the ordinary composition of the metal. In the case of non-ferrous alloys Arnold§ showed in 1898 the possibility of failure due to deterioration or dezincification of brazing solders and Muntz metal. In 1903 Milton and Larke,‖ in a Paper on the decay of metals, gave many instances of deterioration in non-ferrous alloys and also in cast-iron. Generally speaking these examples represent definite chemical change in the composition induced by external causes. With steels any evidence of chemical change is not easily found, and although physical changes are apparent these cannot be explained on the ground of definite change in composition. It is not easy to follow the brittleness induced in steel when subject to corrosive action, for not infrequently a series of factors may be operating together, and it then becomes difficult to isolate one single factor. This aspect is of particular interest in the case of rails, and in order to get a good starting-point a number of new and unused rails have been tested in various ways. Results obtained from two rails are given here, and it is hoped to publish others when later stages of the work have been further advanced.

Tensile Properties.—The method followed was to cut an 8 in. length of rail in order to obtain values corresponding to different zones. This was known as rail No. 11. Another rail (No. 6) of a slightly different character was cut for tensile tests. The adjoining piece of rail No. 6, from which the tensiles were cut, was machined up into bars of $\frac{3}{8}$ in. diameter. These bars were tested for (1) resistivity, (2) alternating stress, (3) a complete analysis of each bar, and (4) a microscopical examination. By the kindness of Prof. Arnold the alternating stress tests were made on his machine at the Sheffield University.

Sections were examined in detail under varying magnifications, but in each instance the structures were quite normal, and are not therefore reproduced. The extent of variation found in rail No. 6 is summarised as follows:—

Table I.—*Summary.—Rail No.* 6.

—	Maximum stress.	Elongation per cent. on 4 in.	Reduction of area per cent.	Alternation of stress reversals.	Specific resistivity. Microhms per cubic cm.
Highest	44·25	20·5	49·0	342	18·5
Lowest	41·75	16·5	43·0	202	17·8
Range	2·50	4·0	7·0	140	0·7

In view of the distribution of metal in the regular rail section the foregoing highest and lowest values are remarkably near to each other, and the range between highest and lowest is comparatively small except in the case of alternation of stress. Here the range is represented by 140, or from 202 to 342 reversals. From many tests the author believes the foregoing summary to very fairly represent maximum and minimum variations in good quality unused acid rails of British manufacture as made in 1910.

Rail fractures in service may be due to initial defects in the steel, or to faults developed by track conditions, by service, or by environment. Experience in this direction tends to support Dudley's observation, that rail failures are a question of geography rather than one of steel-making. A series of fractured rails have been examined, and two of these may be quoted here. Rail No. 11 gives the following summary:—

Table II —*Summary.—Rail No.* 11.

—	Maximum stress.	Elongation, per cent. on 4 in.	Reduction of area, per cent.
Highest	50·25	21·0	42·0
Lowest	49·24	18·0	39·2
Range	1·01	3·0	2·8

Another fractured rail of the same type gives the following range:

Table III.—*Summary.—Rail No.* 13.

—	Maximum stress.	Elongation, per cent. on 4 in.	Reduction of area, per cent.
Highest	50·58	21·0	45·6
Lowest	48·82	17·5	39·0
Range	1·76	3·5	6·6

Nos. 12 and 13 had developed cracks through defective track conditions, and in both cases the cracks led from the bolt holes of the fish plate. Under such conditions, apart from the actual defect developed, the rail shows no sign of decay or deterioration. Under other conditions rails become seriously embrittled, and observation has shown this to be specially so in the case of tunnel rails, and the effect is intensified in damp tunnels. Rail No. 4 which had been in tunnel service is included for comparison with Rail No. 6. The summary is as follows:—

Table IV.—*Summary—Rail. No.* 4.

—	Maximum stress.	Elongation per cent. on 4 in.	Reduction of area. per cent.	Alternation of stress. reversals.	Specific resistivity. Microhms per cubic cm.
Highest	59·25	15·0	32·5	276	21·9
Lowest .	42·50	1·5	2·0	4	19·5
Range	16·75	13·5	30·5	272	2·4

The previous history of this rail is not known to the author, but it presented no steel-making flaws or defects, and so far as can be judged is comparable, except in the matter of service, with rail No. 6. The hardening effect, as shown by the highest maximum stress and lowest elongation, is readily apparent. The rail has been rendered decidedly brittle by its environment and service conditions. Other similar instances have been noted, but it has not yet been ascertained how the brittleness progresses into the interior of the rail. Whilst the whole of the results show the embrittling effect, no two samples are precisely alike, and the author has not been able to trace any regularity in the order of development of brittleness. So far, it can only be said that the deterioration of the uncorroded metal, whilst erratic in intensity, is still certain in effect.

The embrittling effect induced by immersion in fairly strong acids is more or less recognised. In many industries, especially that of wire-drawing, acid cleaning is followed by heating in order to remove scale formed. The following tests were made on rail steel rolled down to ⅜ in. rod for convenience in testing. Each result represents the mean of several tests, and unless otherwise stated the rods were immersed only until the scale was removed, then washed in running water and dipped into lime water. The results are given in the following table:—

Table V.—*The Effect of Acid Cleaning on Steel as Judged by the Arnold Alternating Stress Test.*

No.	Treatment.	Alternating stress test reversals.
10	Cleaned by sand blast	200
11	„ in pure sulphuric acid, 1·5 per cent. water	58
12	„ in pure hydrochloric acid, 2·5 per cent. water	47
13	„ in pure acetic acid	59
14	„ commercial spirits	101
14A	„ „ „ and blued	200
14B	„ „ „ and heated to 800 deg.	225
15	„ „ salts	102
15A	„ „ „ and blued	190
16	„ „ „ twice normal time	80
16A	„ „ „ twice normal time and blued	140
16	„ „ „ thrice normal time	53
17A	„ „ „ thrice normal time and blued	100

Nos. 10 to 13 represent laboratory results, and Nos. 14 to 17A were cleaned in an ordinary wire-cleaning house. Bluing represents stoving overnight at a temperature of from 100°C. to 150°C.; and in the case of No. 14A this treatment has sufficed to eliminate absorbed hydrogen, and to restore the material to its original properties. That permanent injury has not followed is shown by the slight improvement following normalising at 800°C. In the other cases permanent injury follows. From a study of many cases it has been found that even slight over-cleaning results in permanent injury. These results have a certain bearing on those shown in the summary of rail No. 4. The degree of acidity is immaterial provided the time of attack is sufficiently prolonged. A slightly acidulated and moist atmosphere will, in course of two or three years, be sufficient to develop brittleness corresponding to that obtained by immersion for a short time in strong acid.

THEORY AND CONSTRUCTION OF PARTIAL-SLOT WINDINGS FOR POLYPHASE GENERATORS.*

BY DR. M. SEIDNER.

Summary.—An account is given of a graphical method of developing the windings on various types of polyphase machines. This is designed to act as a useful aid in the construction of such windings as employed in practice. The theory is applied to a number of different types of commercial machines.

Modern alternators are, in general, constructed with two, three or four-slot windings; that is, they have two, three or four teeth per pole per phase. When erecting new machines in a systematic and rational way it may, however, happen that the builder, in order to employ the dies which he has in stock, is forced to use a solution which, while combining the number of poles, frequency and speed, leads to a dissymmetry in the number of slots per pole per phase. That machine is wound on the partial-slot system, and such cases are often met with. A partial-slot wound machine is obtained when a three-slot three-phase alternator is converted into a two-phase alternator, the number of poles remaining the same; when a generator with a specific speed is adapted for a different number of poles or another frequency; or when a generator is required to run at different speeds with the same frequency and number of poles. It may also happen that, in a certain type of machine, two teeth per pole per phase are not sufficient, while three are too many. In such cases it is advantageous to use 2·5 teeth per pole per phase. Lastly, partial windings can be used in all cases where machines have to be built with one to two teeth per pole per phase in order to cheapen the manufacture or for other special reasons. Partial-slot windings have also the property, as will be shown later, that the E.M.F. induced in them follows more closely the laws of harmonic motion than does that in an ordinary winding with the same total number of teeth.

In the usual full-slot winding the topographical distribution of the teeth belonging to the respective phases and poles is identical. The winding factors of the respective phases and the angle and size of the vectors of the E.M.F.'s induced in each phase are equal. The system is therefore symmetrical. With the partial-slot winding, on the other hand, the topographical distribution under the respective poles and phases is not consequently identical, so that the vectors of the E.M.F. in the phases may differ both in value and phase. The distribution of the teeth has now so to be combined that the phase voltages and angles are as nearly as possible equal. Another problem is so to distribute the teeth that the winding is simple, and that with former windings as few patterns as possible are necessary. With former windings, too, attention must be paid to the possibility of separating the machine.

Researches on the counterbalancing of the phases, the determination of the winding factor of the single coils, and the settlement of the time relations of the resulting phase voltages can be made mathematically. By calculation, the projections of the vectors of the induced E.M.F.'s in the corresponding teeth can be resolved along two orthogonal axes. In this way their vector sum can be obtained, whose ratio to the absolute value of the vectors gives the winding factor of the fundamental harmonic. In the same way the winding factors of the third, fifth, &c., harmonics can be obtained with the

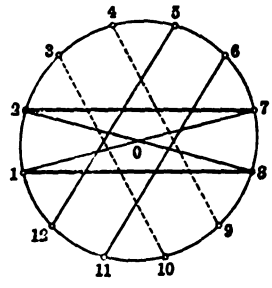

Fig. 1.

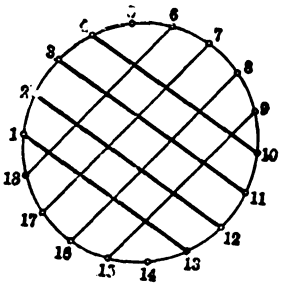

Fig. 2.

difference that the angle of inclination between the components which it is desired to add is three, five, &c., times the angle employed when calculating the fundamental harmonic.

Graphical Representation of the Windings.

In this way, therefore, it is possible to determine accurately and to analyse the winding mathematically. Mathematics is, however, primarily an absolutely indispensable aid to the critical analysis of actual windings. The constructor uses graphical methods with more success, for they make it possible for him to construct a picture of the actual winding, thus facilitating and developing the combination. Having regard to this circumstance, the author has worked out a graphical arrangement to act as a useful aid in the construction of such windings as are employed in practice.

In Fig. 1 is shown the circumference of a three-phase generator wound on the two-slot method. It is thus divided into twelve equal parts. Teeth 1, 2 and 7, 8 belong to phase I., 3, 4 and 9, 10 to phase II., and 5, 6 and 11, 12 to phase III. If the radius of the circle represents the maximum value of the E.M.F. induced in one tooth, then the diameter drawn between the points of division represents the corresponding E.M.F. from which the momentary value may be determined. The diameters are also the vectors of the corresponding E.M.F.'s, and the sum of the E.M.F.'s in any one phase can thus be determined from the corresponding vectors. The resultant of any two vectors can be determined, and taking this property into account the division points of opposite polarity in the respective phases can be connected up as desired. These connections should be made with a view to obtaining the best results.

In the foregoing case a general picture can be obtained when the corresponding points of opposite polarity in the respective phases are connected by means of parallel chords, as shown in Fig. 1. Vectors 1 to 8 and 2 to 7 are in phase I., 3 to 10 and 4 to 9 in phase II., and 5 to 12 and 6 to 11. in phase III. Hence it is clear that the resultant vectors of the respective phases are at an angle of 120 deg. to each

* Abstract of a Paper in the "Elektrotechnik und Maschinenbau."

Digitized by Google

other. Further, the resulting vectors belonging to the respective phases are equal in value. These windings are therefore symmetrical.

The vector diagrams given apply only to two poles. With full slot winding the distribution of the teeth under the respective poles is identical, so that the diagram exhibits the phase relations of the winding for the whole machine. When, however, in multipolar machines, the distribution of the teeth is such that the same tooth arrangement is only repeated after more than one pair of poles, it becomes necessary, in order to determine the vector values proportionate to the resultant phase voltages, to take into account as many circuits as there are pairs of poles, until the original tooth distribution is repeated. It is then possible to sum vectorially the resultants obtained from the respective calculations. These circles can now be superposed, or, in other words, the whole operation is identical to arranging the teeth under different poles, as if they were under two poles in accordance with their topographical position.

If the number of teeth per pole per phase is z, under p poles per phase there will be zp teeth, and the total number of teeth in q phases will be zpq. The same tooth arrangement is therefore repeated after that number of poles for which the product $zpq = c$ is the least whole number. This gives:

$$zpq = c \text{ min.}$$

The winding and vector diagram can naturally be completed only for even-numbered poles, so that in the equation

$$zq = \frac{c}{p}$$

the value of p is always an even number. The vector circle is divided into c parts. The diagram contains the total number of teeth, zpq, under p poles, which, however, should be reduced to that under two poles, so that in the two-pole vector diagram $zp/2$ teeth per pole per phase occur. Each division corresponds to one tooth. With full-slot winding the vector circle must be divided in a corresponding

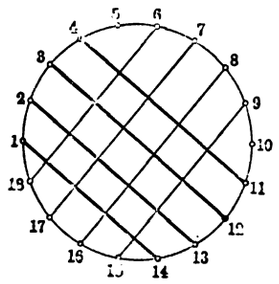

Fig. 3.

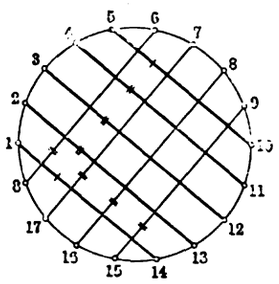

Fig. 4.

manner to the number of teeth from two poles. On the other hand, with partial-slot winding the vector circle must be divided into as many parts as there are teeth under each repeated group of poles. The number of divisions is in most cases greater than with the full-slot winding. For this reason the induced E.M.F. curve with partial-slot winding corresponds more nearly to sine form than does a full-slot winding with an equal number of teeth.

When, however, the number of poles in which the slot distribution is repeated is employed as the minimum number of poles, there is no guarantee that the induced phase voltages and phase angles will be equal. Such equality is only certain when $zp/2$ is a whole number. In this case the vector diagram in all three phases will be completely symmetrical.

If the number of teeth per pole per phase of the machine $zp/2$, when reduced to two poles is an odd number, the division points of the vector diagram can be no longer joined. In this case the winding can only be effected when each phase has not an equal number of teeth, or when certain slots are left empty. In order to make possible the connection when there are an equal number of teeth in each phase without leaving certain slots unwound, the smallest value of n must be found for which

$$\frac{zp}{2}n = \frac{z}{2}\mathrm{P}$$

is a whole number. This means that the vector diagram will be completed when the number of poles is $np = \mathrm{P}$, so that each division of the diagram will represent n teeth. The divisions of the vector diagram may then contain the teeth of the two different phases. The original vector diagram will then be again analysed.

After the diagram, reduced to two poles, has been drawn out and the division points relating to the respective phases have been connected together by suitable means, the vectorial sum of these vectors must be determined, and the resulting vectors equalised with regard to length and direction. If these latter correspond, the p pole winding arrangement can be found from the two-pole diagram. For this purpose the dividing points of the diagram are numbered, each dividing point receiving n numbers. The number of each $np/2$th point is now noted progressively with its phase. In this way the tooth arrangement for a machine with p poles is arrived at.

If the number of slots for a machine with q phases is written down in q horizontal rows, so that the vertical columns give the division of the slots per phase lying under the respective poles, it is then possible to obtain a very clear picture of the winding.

Practical Partial-Slot Windings.

Two-phase 4·5 Slot Windings.—A two-phase winding with nine teeth per pole is known as a 4·5 slot winding. Such a winding is obtained when a three-phase three-slot-wound machine is changed into a two-phase machine without altering the number of poles. In this winding the number of teeth per pole per phase, $z = 4{\cdot}5$, the number of phases $q = 2$; so that $qz = c$ $p = 4{\cdot}5 \times 2 = 9$. Now c, the number of teeth, and p, the number of poles, must be so arranged that with p the smallest even number the value of c is a whole number. If $p = 2$, then $c = 18$. The vector diagram, when $p = 2$, is therefore drawn out, and

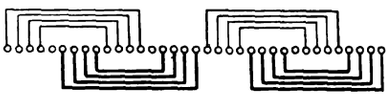

Fig. 5.—Diagram of a 4-Pole Two-Phase 4·5 Slot Winding with Four Empty Slots.

the circle divided into 18 parts, c being 18. In a two-pole vector diagram there are $zp/2 = 4{\cdot}5$ teeth per pole per phase, which is a whole number when $n = 2$. It follows that the minimum number of poles for which the winding can be completed without leaving any slots free is $np = 4$.

It may not be without interest to analyse this winding first in the case when some slots are left free. The circle in Fig. 2 is divided into 18 parts for two poles. The connections for two poles can be differently arranged. It is, however, quite clear that the vector of the two phases neither correspond in value nor in angle. If slots 5 and 14 are left empty, and the then remaining divisions connected, the resulting vectors of both phases will be truly equal but will not be at right angles to one another. If the phase angle is made 90 deg., the values of the two vectors will be very different the one from the other (Fig. 3). If a bipolar solution only is required, the latter is the more suitable. In this case the difference between the resulting vectors is not large, when slots 5—10 are left empty. The difference between the phases is about 1·5 per cent.

In the other case the vectors of both phases are equal but the angles differ by about 10 deg. Naturally, so great a difference is not permissible. In the four-pole arrangement in the diagram in Fig. 4 each division represents two teeth, one tooth in each of the divisions 5, 10, 14 and 1 being left free. Between the resultant values of the phases stands the relation $\cos(10°) = 0{\cdot}98481$, that is the second phase is about 1·52 per cent. greater than the first, as in the former case. The winding diagram for this case is given in Fig. 5.

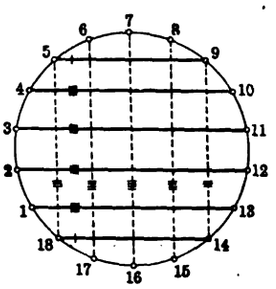

Fig. 6.

By using eight poles the difference between the phases can be reduced practically to zero. With eight poles each point of division represents four teeth, and the divisions 5, 10, 14 and 1 each contain two teeth. It is known that the resultants of the second phase is greater than the resultant of the first phase. If the free slots are so filled up that the shorter vectors 1 to 5 and 10 to 4 and the shorter first phase contain the longer vectors 5 to 10 and 1 to 14, the difference between the phases can be shown by calculation to be only 0·15 per cent. (Fig. 6). A diagram of the eight-pole winding is given in Fig. 7.

To sum up, it will be seen that the two-pole two-phase 4·5 slot winding for two poles can be arranged in such a way that one slot is left free under every pole. In this case the angle between the phases is 90 deg., while between the vectors of the phases there is a difference of 1·5 per cent. With an eight-pole arrangement, all the slots can be used, and there is practically coincidence between the phases. The head connection of the windings can be effected in two planes, and the machine is therefore divisible into two parts.

2⅔-Slot Winding.—The opposite problem to that given above is presented by the three-phase 2⅔-slot winding which is obtained when a two-phase machine with a four-slot winding is converted into

Digitized by Google

three-phase machine with an equal number of poles. In this winding $z=2\frac{2}{3}$ and $q=3$, so that $c/p=3\times 2\frac{2}{3}=8=16/2$, and the tooth distribution is repeated every pole. The vector diagram is divided into 16 parts. Only when $n=3$ is $\frac{1}{2}nzp$ a whole number, and each division will then represent three teeth. The difference between the vectors is shown by calculation to be about 1 per cent. Such a difference between the angles is permissible in a machine with a large voltage drop. The winding scheme is given in Fig. 8, the main connections being arranged in three planes.

It follows, therefore, that a $2\frac{2}{3}$-slot winding can only have an equal number of teeth per phase when there are at least six poles. With

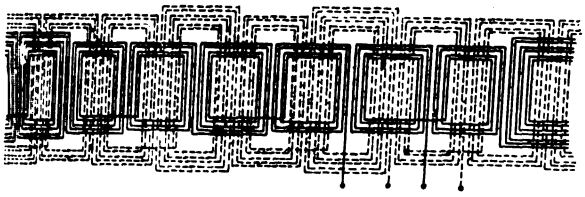

Fig. 7.—Diagram of an 8-Pole Two-Phase 4·5 Slot Winding.

the six-pole arrangement neither the E.M.F. induced per phase nor the phase angles are equal. With an 18-pole arrangement the difference between the phases is reduced to a very small value, so that they are practically symmetrical.

Three-phase 2·5-Slot Winding.—A very frequently used partial-slot winding is the 2·5-slot winding. It occurs in cases where a 42-frequency generator has to be turned into a 50 frequency generator, keeping the number of poles and speed the same. The number of teeth per pole per phase must be altered in the ratio 42/50, so that a three-slot winding becomes a 2·5 winding. The number of teeth per pole per phase is $z=2·5$, the number of phases $q=3$, so that $c/q=7·5=15/2$, so that the teeth distribution is repeated every pair of poles. As, however, $zpn/2=5n/2$, only when $n=2$ is this factor a whole number. It follows that a winding without empty slots can only be arranged on this system with more than four poles.

The three-phase 2·5 tooth winding can be arranged by leaving every third slot in the two-pole arrangement free. To have every slot filled the lowest number of poles is four or some multiple thereof. The winding is in every case absolutely symmetrical.

4·5 Three-Phase Slot Winding.—If the machine speed is altered in such a way that the number of poles must be changed from 12 to 8, a 4·5 wound machine is obtained from a three-slot winding. In this winding $z=4·5$ and $q=3$, so that $c/p=13·5=27/2$. That is the vector diagram must be divided into 27 parts. As, however, $zpn/2$ is only a whole number when $n=2$, it is clear that such a winding can only be arranged for a machine with four or more poles.

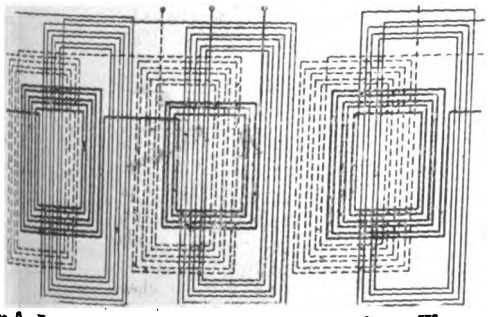

Fig. 8.—Diagram of a 6-Pole Three-Phase $2\frac{4}{5}$ Slot Winding.

Three-Phase 2·4-Slot Winding.—This winding seems very complicated, but is in reality very simple. In this case $z=2·4$ and $q=3$, so that $c/p=7·2=72/10$. That is the same slot distribution is repeated every fifth pole, and the vector diagram must be divided into 72 parts. As $zpn/2=12$ is a whole number when $n=1$, it is clear that this winding is symmetrical for all three phases, that is, the voltages induced in the single phases are equal while the phase angles are 120 deg. With 10 poles this arrangement gives absolute equality between the phases.

THE SEMI-AUTOMATIC METHOD OF HANDLING TELEPHONE TRAFFIC.*

BY E. E. CLEMENT.

Summary.—The author describes a semi-automatic system of telephony which is in use in several towns in America. The subscriber asks for a number in the usual way and the connection is then made automatically by an exchange operator pressing appropriate keys. A comparison of the results obtained by this system and the ordinary manual arrangement is given.

The author begins his Paper by comparing the automatic and manual systems and shows that when a large amount of junction line work is necessary, the cost of the latter system as compared with the former is unnecessarily high. Further, in the full automatic system, though certain advantages are obtained, certain other disadvantages are introduced; it substitutes the untrained subscriber for the highly-trained operator without saving more than 50 per cent. of the running costs under the most favourable conditions and allows certain faulty calls to go through which would be prevented on the manual system.

The fundamental principal underlying the Clement auto-manual system is that the calling subscriber should be met at once by the response of a human intelligence which can direct the proper automatic agencies to satisfy his wants; or, in other words, that the correct method of handling telephone traffic is to sell service and

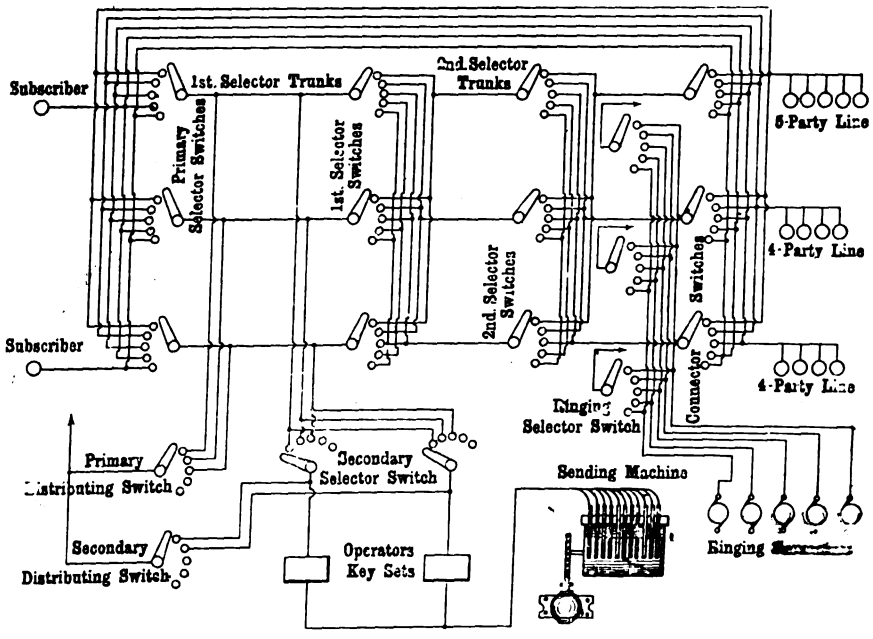

Fig. 1.—General Arrangement of Auto-manual Exchange.

not rent apparatus. Stated broadly, the auto-manual is a combination of the manual and automatic methods which contemplates the centralisation of automatic apparatus; the employment and concentration of operators; and the correct sub-division of a system for traffic handling.

The apparatus is all concentrated at exchange centres, the subscribers' lines and telephones being reduced to the common battery type. The sub-station construction, and the connection and distribution of lines at the exchange centres are the same in the auto-manual system as they are in any modern standard common battery system. With regard to the operators they are restricted to the only function requiring intelligence, that is, ascertaining the subscriber's want and setting up a signal by which automatic apparatus may be caused to supply that want. It is possible to concentrate all the operators at a single operating centre, which can take care of all the switching or exchange centres in a district or even in an entire city, handling all calls with maximum efficiency, and giving uniform service, 24 hours per day, regardless of the nature of the calls or the time of calling.

The accompanying illustration (Fig. 1) is a simplified skeleton diagram showing the general lay-out of an auto-manual exchange equipment having a capacity up to 10,000 lines. In this diagram, five subscribers' lines are shown, one of which is a five-party line, two others are four-party lines and the remaining two are individual lines. Ringing is supposed to be five-party selective. For the sake

* Abstract of a Paper read before the American Institute of Electrical Engineers.

Digitized by Google

of clearness only the most elementary forms of apparatus are shown. The switches, however, are supposed to represent two-motion, 100-point, electromagnetically-driven, step-by-step automatic units, of uniform type. Percentage trunking is employed throughout the system shown, and the switches are equipped with banks containing 10 vertical rows of 10 contact pairs each. The motion is around and up, this precedence of the rotary motion affording certain advantages. The entire system is built up of interchangeable units. The individual or unit switch is composed of a certain number of interchangeable units, such as the spindle with its wipers, the frame, and the interchangeable operating magnets; each switch or trunk circuit, such as the primary and first selector, the second selector and the connector equipment, is assembled complete as a unit, the latest designs having steel mounting plates upon which the unit switches with their relays, condensers, &c., are mounted and wired up complete, previous to being assembled on the racks; a sufficient number of switch plates, with the line and cut-off relays, lamp strips and other accessories, are mounted on a frame section to form a 100-line unit; and finally these 100-line unit frames are aggregated to build up the full exchange equipment, adding thereto, of course, the operators' and wire chief's desks, power plant, &c.

In Fig. 1 the circuits have been laid out so as to show in a simple way the analogy between this system and a manual switchboard system, the same operations being performed in the same manner throughout, but automatically instead of manually. For example, the subscribers' lines terminate on primary selector bank contacts which correspond to the answering jacks of the manual board, and they are also multipled to calling contacts in the banks of the connector switches, which correspond to the multiple jacks on the manual board. The wipers of the primary selector switches constitute the equivalents of plugs which co-operate with the subscribers' answering jacks, but are mechanically driven instead of by the hand of an operator. The first selector switches similarly correspond to the calling plugs of manual pairs, and the first selector trunks extending between the primary and the first selector switches are the equivalents of the cord circuits. The second selector and connector trunks are the same as trunk lines between different positions on a switchboard, the method of switching at each step corresponding to the selective insertion of another plug to add another link in the connection by a manual operator. The secondary selector switches constitute the equivalents of the operators' keys associated with the cord circuits, and the sending machine operated thereby sends impulses to work the selector and connector switches, instead of spoken words to direct an equivalent number of successive operators. The primary distributing switch performs the function of the operator's mind in selecting an idle cord circuit for any given connection, and the secondary distributing switch is the equivalent of a monitor distributing calls among the operators, by directing each one of them when to answer. The ringing selector switches take the place of the selective buttons of "B" or trunk operators so that the selection of the desired generator to ring a particular subscriber is directed by impulses from the sending machine, instead of by spoken words proceeding from the original or "A" operator. To complete the analogy, the releasing means for all the switches when in service are controlled by the connected subscribers, thus corresponding to the supervisory signals, by which in a manual system the subscribers can instruct the operators to clear out. All subscribers' lines are represented by terminals in the primary selectors and in the connector banks.

The progress of a call is from the calling subscriber through an idle primary selector, which becomes automatically attracted to his line, and thence through a secondary selector, similarly attracted, to an idle operator. Under no conditions is this departed from. The principle is that the operator should be brought into direct touch with the subscriber at the very outset, precisely as in a manual system. Having ascertained the number, the operator sets up this number on her key set (Fig. 2) and sends impulses through her circuit to the first selector, second selector, connector, and ringing selector switches, thus establishing the wanted connection, and also starting agencies in the connector circuit which continue thereafter automatically to ring until the called subscriber answers or the calling subscriber hangs up the receiver. After initiating the call, the calling subscriber's line is connected through the primary and secondary selector switches to the operator in every case, and further movement of a subscriber's hook or the repeated opening and closing of the circuit will not reach more than one operator, and cannot disturb general traffic conditions. This happens sometimes through change of purpose or the like, and it is highly essential that the auto-manual operator should not experience the slightest delay, nor pay attention to anything except the rigid rule of getting the number and setting it up. After the operator has answered, the calling subscriber is given full control of the connection, and can clear out and release all the apparatus at any time up to the moment when the called subscriber answers. Thereafter, the called subscriber assumes control of the connector switch, which he can release so as to clear his line by merely hanging up his receiver. This prevents tying up the called line.

When the operator connects the sending machine to the switches, through her key set, impulses are sent in groups corresponding to the several keys depressed, that is to the number wanted, as well as to the number of the generator required to ring the wanted party, if it be a party line. The first group of impulses steps around the first selector switch to pick out a group of second selector trunks, and an idle trunk in that group, leading to the wipers of the second selector switch. The second group of impulses works this second selector switch and picks out a group of connector trunks, and an idle trunk in that group, terminating on the wipers of a connector switch in whose banks appear the terminals of the wanted line. Successive groups of impulses are then transmitted to step the connector wipers round and up to the wanted line terminals.

Associated with each connector switch is an auxiliary or ringing selector, having a wiper sweeping over terminals which are connected to several ringing generators, as shown, each of which supplies current at a distinctive frequency.

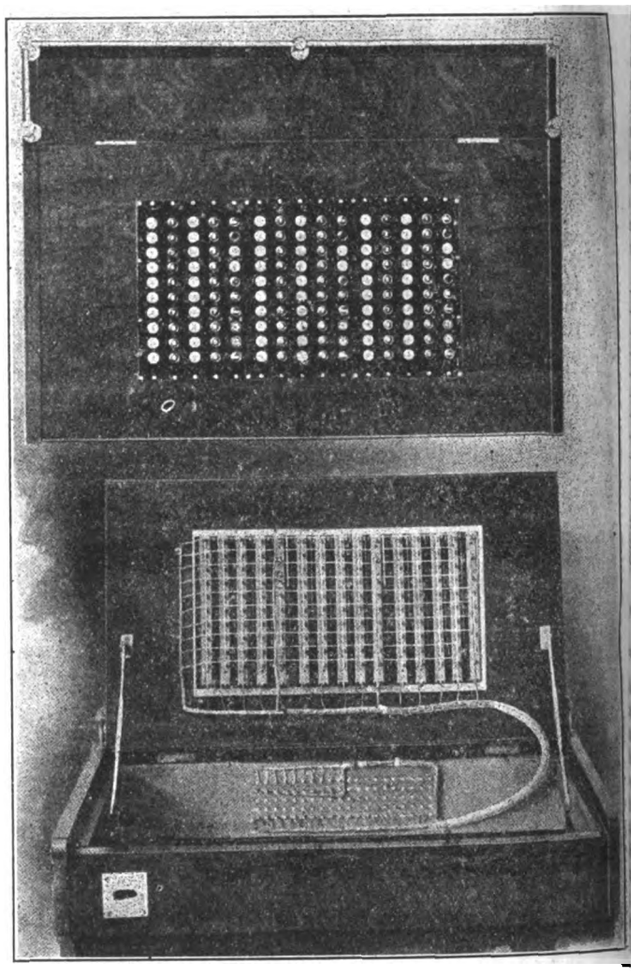

FIG. 2.—KEYBOARD OF CLEMENT AUTO-MANUAL SYSTEM.

At the last stage in a connection, when the wanted subscriber's line has been picked out by the connector switch, and the ringing selector has been set so as to bring into service the proper generator, that generator is then automatically connected by a ringing relay to the subscriber's line to ring his bell. At all other times the ringing selector remains disconnected.

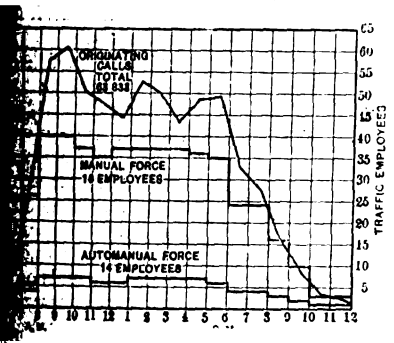
The control of the primary selector switches is through relays on the switch racks, responsive to line current. These relays complete local circuits to place test potential on the test contacts of the primary selector switches, and at the same time close starting circuits for the idle trunks and operators. A type of relay is employed both for the lines and switches, which is the result of much thought and experiment. This relay has its armature bent over at both ends, the inner end being screwed to the rack, and the outer end carrying the adjustment for the magnet core. The bell crank armature is dropped through a slot punched in the main armature near the rack end, and the springs are mounted on this same end, so that both the armature

Digitized by Google

lever and the springs extend forwardly. This construction gives a long leverage with a very small air gap which is essential for this class of work, and also exposes the core adjustment and spring contacts.

The operation of the secondary selector switches is essentially the same as that of the primaries. As soon as the primary distributing switch has determined the primary trunk to be connected to the calling line, the secondary or operator's switch tests until it reaches the trunk, where it stops, and remains connected to the trunk until finally released, which may be by the calling subscriber hanging up after the operator has answered, or at the conclusion of a cycle of impulses, whereby a complete connection is established. The interrupters and sending machine are timed so as to deliver at the rate of about 1,000 impulses per minute, with the battery voltage normal. Any drop in the battery which would affect the switches is compensated by a corresponding drop in speed of the sending machine. At the normal speed stated, however, a high number line in the calling group and a high number trunk in the corresponding group, can both be found and connected in less than one second and a half. Where the numbers are low the action is practically instantaneous.

Each operator has three key-sets mounted on a suitable desk, each associated with it certain signals which guide the operator in the discharge of her duties. The key-set in general appearance is quite similar to the keyboard of an adding writer, consisting of a number of strips of 10 keys from 1 to 0 in each vertical row. One of the keys with these keys is a calling lamp, which is lighted when the key-set becomes connected through switch to a first selector trunk already connected to a call. Observing the signal, the operator asks the subscriber number wanted, and proceeds to depress the corresponding buttons. She then presses a separate starting key,



...SON BETWEEN THE OPERATION OF A MANUAL AND AUTO-MANUAL SYSTEM.

...employees in manual force should apparently be 61.—ED. *E.*]

...impulses, corresponding to the buttons depressed, will be transmitted as already stated. The wanted subscriber's bell is automatically rung at intervals until the call is answered, but in the meantime it is both unnecessary and undesirable to hold the operator, and so the secondary switch is cut off from the line by the sending machine as soon as the ringing starts. The duplicate sending machines are arranged with changeover gear enabling either to be thrown in or out in case of breakdown. Each machine comprises a cam drum working 10 pairs of contacts, with separate controlling contacts and a commutator. On one side the commutator is earthed and on the other is connected to all of the number spring sets, and the number cams are so arranged that in the rotation of the drum they make and break at the zero potential on the commutator, thereby avoiding sparking at the collective terminals. The operator's key set is normally disconnected from the sending machine, but is connected thereto when the starting button is pressed, by means of a switch or relay, after the whole number of groups of impulses has been transmitted. The secondary selector is released automatically. The operation is the same when junction lines have to be used.

A comparison between a manual and an auto-manual operating system handling a traffic load is shown in Fig. 3. This traffic load is that of 4,162 working lines connected with a main and a branch exchange located in a western city. About 21 per cent. of all calls originated are trunked. The calls handled during the busy hour in the busiest months average about 185 per manual operator.

	THE AUTO-MANUAL FORCE.
...ation.	2 chief operators
...erator	1 relief operator
...tors	11 operators
61 employés	14 employés.

It will be noted that the manual "B" or trunk operators and the trunk calls are omitted from this chart. The auto-manual makes its greatest saving where branch exchanges are employed; the heavier the trunking, the greater the saving with auto-manual because it eliminates trunk operators. Notwithstanding that the chart deals only with "A" operators, a reduction in employés in favour of auto-manual amounting to 77 per cent. is nevertheless effected.

THE DETERMINATION OF LONGITUDE BY RADIO-TELEGRAPHIC TIME SIGNALS.*

BY M. TISSOT.

The constant care of the navigator is to know at each instant his position. Observations of the stars easily furnish the latitude; but the longitude may only be obtained from the difference of two angles, and its determination necessitates a knowledge of the local time and the time of the meridian origin—Paris, for example. It is this last determination which gives the difficulty, as local time is furnished by observations of the stars with the same facility as latitude.

As everyone knows, the time of the meridian origin is obtained by means of a chronometer which the navigator carries with him. Everything depends on the quality of this chronometer and the more frequently it is checked the greater will be the confidence one may have in its indications. If these checks can be obtained at sufficiently short intervals the *quality* of the chronometer will have lost its importance.

During the course of experiments undertaken by the Commission Centrale de la Marine, in November, 1907, it appeared, amongst other results, that our ships received with perfect regularity the signals emitted by the Eiffel Tower, in the Mediterranean and on the Atlantic coast of Morocco. From this I thought of proceeding to a series of systematic trials in order to find out under what conditions it was possible to utilise the Eiffel Tower station

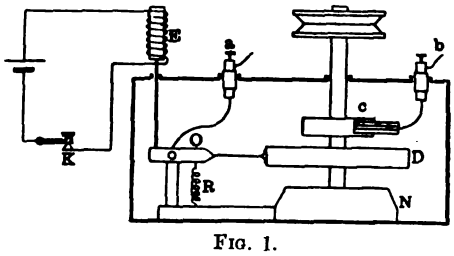


FIG. 1.

for the transmission of time signals. Thanks to the collaboration of Commandant Ferrié, it was possible to execute these experiments between the Eiffel Tower and Brest in December 1907.

The trials consisted in obtaining by the aid of "dots" sent from the Tower, the comparison of chronometers of known rates, placed at each of these stations. Very concordant values were obtained, agreeing to 0·5 sec.; an approximation amply sufficient for ships. As a result of these experiments, a service of regular time signals was commenced in May, 1910.

The signal consists of a "dot" emitted at midnight—Paris mean time—preceded by a *call* signal. This is repeated at 2 min. and 4 min. past midnight. The call signal is sufficiently characteristic to render confusion impossible and is actuated by hand with a Morse key; but the real time signal is controlled automatically by a clock at the Observatory of Paris.

The emission from the Tower necessitates the making and breaking of a current of 50 amperes by means of a device actuated by a relay controlled from the Observatory. This is done by a mercury jet interrupter designed by Commandant Ferrié. A small turbine forces mercury under pressure through a tube pivotted on a horizontal axis O (Fig. 1). By means of a spring, R, this tube is, normally, directed towards the fixed part, N, of the turbine. On closing the key, K, a current in the coil, E, attracts a plunger causing the tube to turn, so that the stream of mercury impinges on an amalgamated copper disc keyed to the axis of the turbine. The main current is thus closed through the mercury jet. On opening K, the jet falls and the current is broken without the production of an arc. To secure a quick break, it should be produced in a liquid dielectric, by filling the turbine with paraffin or alcohol.

With the assistance of M. F. Pellier, I have produced a very easily managed receiver, suitable for small ships, the low cost of which enables it to supplant an expensive chronometer.

* Abstract of an article in "La Technique Moderne."

Digitized by Google

It consists of an Oudin resonator (Fig. 2) of rectangular form, the secondary of which is fixed and constitutes, with a condenser, C, also invariable, a resonating circuit, tuned once for all to the period of the waves emitted from the Eiffel Tower. A detector is inserted in this circuit with a telephone across its terminals. The primary is inserted between the antenna and the earth and consists of the part of this solenoid between M and the sliding contact, A. This sliding contact is moved until the sound in the telephone is a maximum. The detector, which is of the solid contact type and requires no auxiliary battery, consists of a fixed electrode (Fig. 3) which is a small piece of sulphide of copper, or galena, and an adjustable electrode consisting of a fragment of zinc oxide; the whole being enclosed in a protecting brass cylinder.

As the time signals make it possible to obtain Paris time every 24 hours, it is sufficient for a ship furnished with receiving apparatus, to possess a good watch to act as daily timekeeper. With the present installation at the Tower, the reception of radiotelegraphic time signals may be considered certain within a radius of 2,000 km.; and this distance will be considerably increased when the new more powerful station is working.

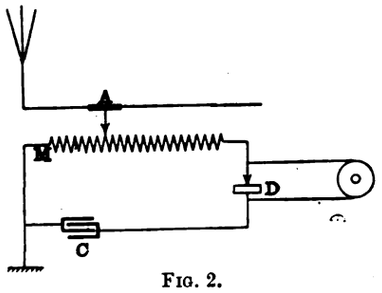

FIG. 2.

The observation of a single "dot" is not sufficient to fix the precise value of a difference of longitude. In order to use the *method of coincidences* a series of periodic signals is necessary. For this purpose M. Claude has adapted the Lippmann pendulum, electromagnetically maintained, in the following manner. Two silver wire circles, *a* and *b* (Fig. 4) are fixed to two supports, *m* and *n*, and are inserted in the circuit containing the cell, P, and relay, R. A small piece of silver carried by the pendulum closes the circuit as the pendulum passes through the vertical. The duration of contact is long enough to secure the working of the relay; this can be regulated by micrometer screws which allow the supports, *m* and *n*, to be displaced. At each beat of the pendulum, the relay is actuated and closes the circuit, E (Fig 1), so that a spark is produced. The successive beats thus gave rise, in the receiving telephone, to a series of ticks.

It is then easy to compare two pendulums placed at any two stations, A and B, by using as intermediary a pendulum at a third station, C. In order to apply the *method of coincidences* the length of the pendulum at C is adjusted so that its time of vibration is slightly greater than that of either of the pendulums to be compared.

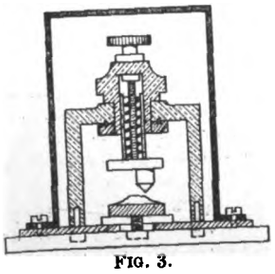

FIG. 3.

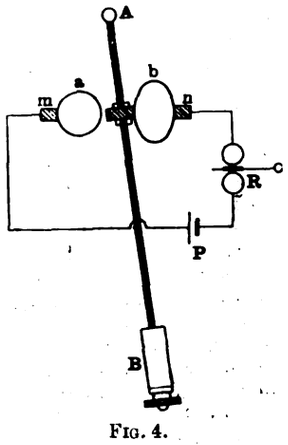

FIG. 4.

This method has been applied to the determination of the difference of longitude between Paris and Brest; the pendulum C being at the Eiffel Tower, A and B at the Observatory at Montsouris and the radiotelegraphic station at Brest respectively.

By the aid of a microphone the beats of a local chronometer were observed in the receiving telephone together with the signals from C.

The microphone is inserted in the primary of an induction coil, the secondary of which is connected to the receiving telephone; adjustable resistances in both primary and secondary make it possible to equalise the intensity of the beats from the chronometer with that of the signals transmitted by wireless telegraphy.

The object of the experiments was not the determination of a difference of longitude already known, but to test the radiotelegraphic method, by comparing two chronometers, one at Paris, the other at Brest, on the one hand by the telephone, on the other, by the beats transmitted from the Tower by wireless telegraphy.

The results were perfectly satisfactory, the difference, if there be one, between the telephonic and radiotelegraphic comparisons being certainly less than 0·01 sec.

THE ELECTRIC DRIVING OF LIGHT ROLLING MILLS.*

BY G. J. HOOGHWINKEL AND F. THURSFIELD.

As compared with heavy reversible mills the problem of light mills is an easy one, although the electric drive for reversible mills is even more advantageous, but the usual bugbears, such as high installation cost and complicated equalising plant, do not enter into the comparison to the same extent. On the other hand, the various applications of electric driving offer a much wider field to the electrical expert if more economy and simplicity is to be obtained.

The question of final economy is a very complicated one, and the case is not quite so clear as in the analogous case of the electric-driven winding engine, because, in the case of the reversing rolling mill, the stored energy of the system cannot be utilised for starting again. The flywheel masses of rolling mills and the radius of gyration are small, and there is no question of direct electric braking, giving energy back into the system, but the mill comes to a standstill almost immediately the current supply is cut off.

The authors indicate how economy in many of the existing steam-driven plants could be obtained by the use of exhaust steam turbines, and then pass on to the consideration of gas engines for this purpose. The first engines in this class of prime mover were invariably too small, and now they are more expensive in first cost than steam engines, though the running costs are about the same, if the value of the furnace gases be taken to be ½d. per 1,000 cubic ft. It is practically certain, however, that the cost of gas is much higher.

From their peculiar properties, electric motors are particularly applicable to mill driving, as compared with steam engines. Until recently the difficulty of speed variation was regarded as an objection to the motor, elaborate arrangements of stepped rope pulleys and screw traversing gears being adopted in some cases. In the last year or two several methods of overcoming these difficulties have been perfected, and satisfactory arrangements for producing three or four different speeds quite economically are now available.

The question of economy entirely depends on circumstances. A large majority of the mills in the Black Country are driven by steam generated from the waste heat of the coal-fired furnaces. With this system ample steam is produced for driving the mill, and the cost of power consists of the attendance and stores, plus the capital and maintenance charges on the engines, the numerous small scattered boilers, and the ramification of steam pipes needed to combine them. Though these upkeep charges are undoubtedly heavy for the power of the plant, they are small as compared with the cost of electrical energy for the work they perform. If, however, the cost of fuel used is taken into consideration, it will be seen that it is a very large item in the production of, say, a ton of rails as compared with the cost of the electrical energy needed for rolling. A ton of rails can be rolled from the ingot for about 60 units, or for, say, 2s., taking current at 0·4d. per unit. With improved regenerative furnaces it should be possible to save at least 2s. per ton of metal in the fuel required for puddling, re-heating, &c.

As to the capital cost, this will not be a very serious item when both electric power and gas can be obtained from a supply company. Taking 10 per cent. on the capital cost of the motors, switchboards, starters, flywheels, couplings, foundations, &c., it should not work out at more than 3d. per ton of finished material, provided the plant is kept fully loaded. This small charge would be more than covered by the saving on the upkeep of boilers, pipes and engines, without taking into account the saving in space effected by the change.

As a guide to the relative cost of upkeep of the two classes of machinery under severe usages, the experience of the Mersey Railway Co. may be quoted, where the upkeep of the generating station plant, conductor rails, motor and all electrical gear is 6 per cent. less per train-mile than the maintenance of the steam locomotives.

It is now generally admitted that an increased output may be obtained from a given mill when electrically driven. This is due to two causes: (*a*) The more even turning moment, resulting in fewer hot bearings, breaking of couplings, &c., and (*b*) the more uniform speed, permitting the average speed to approach more nearly to the maximum. Both these causes favourably influence the quality of material produced.

* Abstract of a Paper read before the Staffordshire Iron and Steel Institute.

Digitized by Google

The economy to be obtained from electric driving will depend very materially not only on the proportioning of the various passes, but on the actual usage of the plant. Where power is supplied by meter from a power company, idle running must be avoided at all costs. The power required to run a mill light is very considerable, and close supervision will be needed to see that the roll train is continuously fed with pieces. Care is also needed to see that not more than the correct number of pieces is allowed in the mill simultaneously, as the consequent overload can only be supplied at some expense in economy.

With reference to the power supply, four cases need only be considered: (1) A supply from a municipality or power company. (2) a supply from the Mond Gas Co., (3) a turbine supplied from existing puddling furnaces or coal-fed boilers, (4) an exhaust turbine supplied from an existing large mill engine to generate electricity for smaller mills and auxiliary plant.

At about 0·4d. per unit the electric drive will be cheaper than the steam drive with modern non-condensing compound engines, taking into consideration repairs, maintenance, wages, 10 per cent. for interest and depreciation, oil, waste, &c. The steam consumption must be taken over 24 hours or over a year, and include all auxiliary machinery. It is this point which is so often lost sight of by the advocates of the steam drive. The writers have found that with modern engines of the best types 35 lb. of steam at 150 lb. pressure per brake horse-power-hour taken over the whole year is a fair average. Taking an 8 ft. and 10 ft. merchant mill rolling rounds and squares at 20 B.H.P.-hours per ton, with coal at 6s. per ton, the fuel costs would be 6·5d., and the total costs, including interest and depreciation, wages, &c., but no repairs and maintenance of boilers and engine, would be, with an output of 30,000 tons, 13·6d. per ton, and with an output of 15,000 tons, 19·2d. per ton.

With electric power at 0·4d. a unit and an overall efficiency of 62 per cent. we get the following: With an output of 30,000 tons, 12d. per ton, and with an output of 15,000 tons, 18·6d. per ton. The repairs and maintenance of the electric motor are, of course, quite small, and the total maintenance, including gearropes, &c., is quite out of proportion to the repairs and maintenance, costs of engine, boilers, pumps, belts, gearing, &c. The corresponding figures for the heavy rail mill at the Hildegarde works is 10·4d. per ton, not including wages. The increased production, and other advantages which have been proved in actual practice, and which have been enumerated before, will turn the scale still further to the advantage of electric driving.

The installation of gas engines to drive the electrical equipment in cases where no electric supply at low rates is obtainable, but where the mains of the Mond Gas Co. are within easy reach, is more or less a special case, and need only be considered in this particular (Staffordshire) district. The first cost of gas engines, dynamos and motor is higher than steam engines and boilers, and, therefore, the capital charges also increase. The full costs are about half and maintenance and repairs are higher than with steam drive. Altogether it will be found that this method of driving does not present any specific advantages in general cases.

By far the most important system of driving in this district, which is bound to engage the attention of works managers in the near future, is the utilisation of the low-pressure steam from the puddling furnaces in steam turbines coupled to electric generators, enabling the larger works to produce their own electric power required for the rolling mills and auxiliary plant. In most works the mill-engines are old and highly uneconomical, the gearing is worn, and last, but not least, there is a general desire to speed up the mills and increase the production per mill. As already explained, the electric drive is inherently adapted to give this increased production, and this more homogeneous product, and the old steam engine is unable to go. The low steam pressure prevents in any case the installation of the more modern but costly compound condensing mill engine, even should this be desirable. The turbine, however, adapts readily of the utilisation of low-pressure steam; it possesses practically unlimited overload capacity, and can be easily regulated.

It is incorrect to say that as steam is a bye-product of the puddling plant it costs nothing, and can be wasted in the old mill engines. This also used to be the colliery engineers' argument when electric winding came to be discussed, and the waste of the old steam winders was pointed out, because slack at the pit mouth would cost nothing. The fallacy of this argument is now readily admitted, and steam at the colliery has been given its true value. The same applies to the waste heat of the puddling plant, especially if puddled bars are produced and sold at a loss in order to keep the waste heat.

A system which will prove to be a considerable advance on existing methods, and which has been worked out for electric-winding engines, consists in driving a single turbine coupled to two generators, one direct current for driving the direct-current motor of two mill trains, and the other a three-phase current generator to drive the auxiliary plant at the works. Only the steam turbine allows such an arrangement owing to its splendid regulation and overload capacity, the boilers acting as the storage system or flywheel in this case. This is a cheap and very efficient arrangement, as the load factor on the turbine is very high. The authors then give details of the various methods employed in applying the electric motor to the driving of

rolling mills. These include both rope, belt and direct drive with flywheels, or gearing may be used. Rope driving is at present the most commonly met, though it has the disadvantage that fluffy matter is given off, while no very great speed reduction can be obtained.

As regards the construction of rolling-mill motors, they should be made with ample bearing surface and with a substantial shaft. Live pressure should be guarded against by the provision of thrust bearings. Commutating poles should be used on direct-current motors.

The Paper concludes with a table giving a list of electrically-driven rolling mills, which we reproduce herewith.

ELECTRIC SMELTING FURNACES AND THEIR APPLICATION.*

BY M. RUTHENBURG.

Electric smelting has emerged from the realm of mere scientific investigation, and has taken a firm foothold in the commercial production of metallurgical and other products, which can be produced either more cheaply or of greater purity from base starting products than by other means; or in some cases it does work or makes products that cannot be produced in any other way. Of furnaces there are many. Their claims to radical superiority, one over the other, except in mechanical detail, may be at once dismissed as existing only in the minds of the inventors and those interested in exploiting them.

The first practical furnace operating under modern conditions was that of Siemens, and all the details of current regulation necessary in an arc furnace, typical of some modern examples, are clearly shown in Siemens' furnace of 35 years ago. It has been well said that "the time has arrived at which the furnace man and the metallurgist should take a hand in the development of the electric furnace." This being so, along what lines should that development be? Whether the furnace be used for refining steel, smelting pig iron, smelting copper ore, smelting complex ores of lead and zinc, smelting zinc, smelting nickel-cobalt arsenides, smelting nickeliferous pyrrhotite, smelting tin ore and tin slags, making alloys of manganese, chrome, titanium, vanadium or silicon, the furnace does not depart from being a mere receptacle or container for holding the raw material to be operated on—the molten product—and means for minimising the radiation of the electrically produced heat.

It may differ in form, in lining, in the means of introducing raw material, the means for removal of product, and means and facility of repair—all of which are of vital importance. The kind of current used, and the means of applying it, are also important. Direct current, on account of commutator troubles, is not used, except for electrolytic work, and the furnaces for such work are of the very simplest description. Single and multi-phase currents are most extensively used, the advantage for electrical and heat distribution being with the three-phase current.

Constant voltage is almost universally used, simply because lighting and power supply demand such regulation, and the smelting supply is taken from the same source, or from a generator that has been designed on the same lines. The latest and best work is done with constant current with automatically regulated non-arcing voltage, using a slag as resistances, the electrodes operating merely as conductors to deliver the current to the slag. The electrodes are usually held by heavy clamps, to which are also attached the flexible leads for supplying them with current. When in the course of use the clamps reach the roof of the furnace, the electrodes can be fed no further and must be replaced by new ones.

The heaviest consumption of electrode is not at the end, and useful; but along the body, and useless. Water jackets around the electrodes remedy this wasteful consumption of carbon. It is quite safe to carry them clean down to the slag, and though the current notion may be to speculate on what will happen if a jacket be cut, long experience shows that absolutely nothing will happen other than chilling the furnace.

The hearth is accessible in all parts for repair, and may be replaced in a few minutes by a spare one. For experimental work, hearths with acid, basic or other lining, may be kept ready, and used in the same furnace at a few minutes' notice for the change.

Other important points in an electric furnace supplied with alternating current are to minimise joints and contacts; have no heavy solid conductors, but split them up. When joints are unavoidable, see that contact is good and of ample area. Conductors should be ample for maximum current—err, if at all, in making them over what is needed. They are bought but once, and their scrap value is high.

The smelting of iron ore electrically is an accomplished fact, and if the same principles that apply to the selection of a proper site for a blast furnace are used, the electrical proposition stands or falls in the same way. Either case resolves itself largely into one of transportation, the items being ore, fuel (power), flux and finished product. That furnace which can gather fuel, flux and ore, and deliver finished product to market with the least *mile tons*, other things being equal, wins. Therefore, every proposition must be worked out on its own basis. Power in Norway may be dear at *any* price if raw material and finished product must be carried in and out, unless electric current is the chief item of expense, and the product cannot be made otherwise.

Copper ores, both carbonate and sulphide, are shipped half around the globe, when, after paying freight, but a small portion of their value remains to pay for the mining and profit. Water power or coal, and in some cases, both, occur in close proximity to the mines; instead of shipping a 20 per cent. to 40 per cent. ore, it should be smelted at the mine to finished anode metal, making much better recoveries than a blast furnace, and doing it more cheaply. In a recent case, the difference in slags made in the electric furnace and the blast furnace amounted to 4s. a ton on 100 tons a day—making a saving of £7,000 a year.

In smelting nickel-cobalt arsenides, great trouble is experienced in roasting, and, if not roasted, an inordinate amount of speiss is made. Electrically smelted, without roasting, the last traces of arsenic are removed, no speiss is formed, and clean slags are made. A second melt delivers the finished alloy ready for sale. In making nickeliferous pig iron, pyrrhotite, carrying 40 per cent. of sulphur and 2 per cent. of nickel, is roasted to get rid of sulphur. This is never complete, and is a laborious job. Electrical smelting drops the sulphur at once to a fraction of one per cent. and a second melting delivers finished pig iron with 3·25 nickel which finds a ready sale among steel makers. That complex mixture of lead-zinc-iron sulphides carrying gold and silver, which has been the basis of more metallurgical schemes than any other, is a beautiful example of the electrical furnace doing what cannot be done otherwise. If the ores occur crystalline, they may be crushed and dressed, the lead separating by gravity, the iron and zinc by magnetic separation. But even with the best of work, the lead has some zinc and iron, the zinc some lead and iron, and the iron some lead and zinc. Only one metal is paid for, and any other value it carries is lost. In the electric furnace the raw ores from the mine, coarse and fine alike, are smelted without admixture of any kind whatever. Lead, zinc and sulphur volatilise and are caught and separated in condensing towers; copper, silver, gold, iron and silica form matte and slag. The matte is bessemerised to anode metal; the lead and zinc, with a second smelting, are made into finished metal.

Tin ores present many difficulties. The ores as they come to market contain many impurities, which, in being slagged, carry a lot of tin with them. The case is complicated by the fact that tin acts as an acid to bases and as base to acids. Besides, the temperature of reduction of stannous oxide by carbon is high, and at this temperature tin volatilises. The first ordinary smelting produces very rich slags, which, after being re-smelted five times, still contain 3 to 5 per cent. of tin. If these slags be smelted in the electric furnace, slags result that carry but 0·25 per cent. tin, recovering the tin as metal, and besides, as a separate product, any other values. Many ores of tungsten, manganese and chromium are low grade, their impurities being mostly iron and silica, frequently chemically combined. These may be separated and the fractions smelted, resulting in pig iron carrying a little of the other metal, and a high grade ferro-alloy of the more valuable metal.

Some of the more fusible metals volatilise badly at the temperature of reduction of their oxides by carbon. Late improvements enable these metals to be reduced at low temperatures with no volatilisation. For this work, the electric furnace is essential.

Central power stations are realising the desirability of an equalising load, and those who fully realise the situation will sell at very low figures, and still profit largely through serving electric furnaces. If the undertaking be of sufficient magnitude, an individual installation is desirable, and may consist of steam turbo-generator sets, or gas engine units.

DISCUSSION.

Dr. J. W. RICHARDS said he hardly liked the statement that Mr. Ruthenburg had made, in regard to using the slag as a resistance, that the furnace should be built with a non-arcing voltage. In using slag as a resistance the current actually went through the metal and practically only met the resistance of the thickness of the slag above the metal. In all the furnaces where electrodes were used, apparently dipping in the slag, there was always an arc beneath both electrodes, and the major part of the heat energy was generated by the arcs at the electrodes.

Mr. F. T. SNYDER thought this was a good time to call attention to the fact that the electric furnace load was not a desirable load for the central station.

* Abstract of a Paper read before the American Electrochemical Society.

FARADAY SOCIETY.

The meeting of the Faraday Society held on May 23rd, at the Institution of Electrical Engineers, Dr. R. T. Glazebrook, C.B., F.R.S., vice-president, in the chair, took the form of a general discussion on high-temperature work. Previous to the meeting, the Society visited the National Physical Laboratory, by the kind invitation of the Director, and inspected the high-temperature equipment described in Dr. J. A. Harker's Paper. Mr. H. C. Greenwood also gave a demonstration of his method for determining the boiling points of metals mentioned in the Paper below.

Dr. A. L. Day, Director of the Geophysical Laboratory, Carnegie Institution, Washington, contributed the first Paper, entitled

"Recent Advances in High-Temperature Gas Thermometry."

The Paper reviews the work done in recent years to increase the range and accuracy of the temperature scale upon which the various methods of measuring high temperatures depend for their calibration. It is very essential to emphasise the limitations of the gas thermometer, on which the fundamental measurements have to be made, because the ease with which relative temperatures are now measured electrically may lead the inaccuracies of the standard scale to be overlooked and the readings of the secondary instrument to be regarded with unwarranted confidence. The gas thermometer, moreover, is limited in range, and in using radiation-pyrometers, or even thermo-elements, for the higher temperatures, there is a temptation to extrapolation of a somewhat irresponsible kind.

The four attempts which have been made during the past few years to measure temperatures above 1,000°C. with the gas thermometer are next described briefly. Harker in 1904 used a porcelain bulb and nitrogen, but 1,150°C. was the upper limit of temperature attained. Jacquerod and Perrot in 1905 used a bulb of quartz glass, whose expansion coefficient is very small, and various gases, which gave concordant figures for the melting point of gold. But all of these were higher than other recent results, and again the absolute measurements did not extend beyond 1,150 deg. Holborn and Valentiner in 1906, using bulbs of platinum-iridium and pure iridium, with nitrogen for the gas, were the first to extend the scale to beyond 1,600 deg., and their work has been continued by Day and Clement (1909) and Day and Sosman (1910) using nitrogen in bulbs of platinum containing 10 per cent. iridium and 20 per cent. rhodium respectively.

The principal features of the modern constant volume gas thermometer are next discussed. *The Gas.*—Nitrogen is now used exclusively, and even at 1,600 deg. there is no irregularity in its expansion or evidence of dissociation. *The Bulb.*—The abandonment of metal for porcelain by Deville and Troost in 1857 was a retrograde step. Porcelain at high temperatures cannot hold the gas, and it does not expand uniformly. The author now uses platinum stiffened with 20 per cent. rhodium, as it is not safe to use iridium in conjunction with thermo-elements at high temperatures. Such bulbs cannot be used above 1,100 deg. *The Furnace.*—Two essential improvements are noteworthy: electrical heating and the author's device of enclosing bulb and heating coils in an air-tight bomb, so that the gas pressure outside bulb may be kept equal to that of the expanding gas, thus preventing diffusion, minimising mechanical strain, and increasing sensitiveness. Electrical heating, while giving a constant temperature, does not necessitate a uniform temperature over the bulb. Below 700 deg. baths can be used to equalise the bulb temperature—it would be worth while to search for a liquid bath that could be used up to 1,550 deg. *The Manometer.*—The open U-tube type is usually adopted. The capillary connection between bulb and manometer may be made so small that errors due to ignorance of its temperature, once of formidable importance, are now negligible. *The Auxiliary Thermo-element.*—As the gas thermometer can only be occasionally employed, a thermo-element graduated in terms of the gas thermometer is usually employed as a secondary standard. As the E.M.F. temperature curve approximates to a parabola, interpolation can safely be employed, and now that direct measurements with the gas thermometer have been made up to 1,550 C., thermo-elements can be relied upon to the same limit of temperature. The Paper contains a table of standard fixed temperatures ranging from 320 deg. to 1,575 deg., which, being the melting or freezing points of metals, minerals or salts, are available for general use. Direct and accurate calibration of radiation pyrometers between 900 deg. and 1,550 deg. is now possible.

An estimate of the melting point of platinum, based on the temperature interval obtained by radiation methods between the melting points of palladium and platinum, gives 1,755°C. ±5°. Extrapolation on a thermal E.M.F. curve gives a mean value of 1,752 deg. for the same point.

The next Paper was by Dr. J. A. Harker, F.R.S., on

"The High-Temperature Equipment of the National Physical Laboratory."

The Paper dealt with the methods of construction and the use of the various forms of apparatus for the attainment of temperatures above 100°C. which have been designed at the laboratory during the past 10 years. For liquid baths the general system adopted throughout, both for these and lower temperatures, consisted in the use of a vessel made up of two parallel vertical tubes, cross connected above and below. In one of these tubes is placed a continuous rotary stirrer, and in the other the apparatus to be heated. The heating may be by gas or electric current. The baths are so designed that the work to be accomplished by the stirrer in equalising the temperature of the different parts is a minimum, and great uniformity of temperature in the working tube is thus attained. Common olive oil is employed between 50 deg. and 220°C., and above that temperature mixtures of fused salts are used, one of the most convenient being equal molecules of KNO_3 and $NaNO_3$, which melts at 219°C., gives off no fumes, and can be used in an iron vessel as high as about 650°C.

The construction of electric furnaces for various temperature regimes formed the subject of the second half of the Paper.

Mr. H. C. Greenwood, M.Sc., then read a Paper entitled

"The Boiling-points of Metals."

In view of the scanty and uncertain nature of our knowledge of these important constants, a general investigation of the question was greatly needed. The present experiments may be divided into three sections:—

1. A study at atmospheric pressure of the boiling points of a number of metals which are unaffected by carbon at high temperatures (antimony 1,440°C., bismuth 1,420°C., copper 2,310°C., lead 1,525°C., magnesium 1,120°C., silver 1,955°C., tin 2,275°C.).

2. A study at atmospheric pressure of the boiling points of some metals which readily combine with carbon (aluminium 1,800°C., chromium 2,200°C., iron 2,450°C., manganese 1,900°C.).

3. The influence of pressures varying from 10 cms. of mercury to 50 atmospheres on the boiling points of bismuth, copper, lead, silver tin and zinc.

The metals were contained in graphite crucibles ("brasqued" with fused magnesia for the metals attacked by carbon) and were heated in vertical carbon tube electric resistance furnaces. For the experiments at pressures other than atmospheric the furnaces were arranged inside suitable enclosures. From the boiling point pressure curves the latent heats of vaporisation were calculated.

Mr. A. Blackie, B.A., communicated a Paper

"On the Behaviour of Silica at High Temperatures."

This communication gives an account of some experiments made to determine the effect of heat on the strength and devitrification of the opaque and transparent varieties of fused silica. A determination was also made of their relative coefficients of expansion at high temperatures.

The test selected as a criterion of strength was the transverse fracture of a small rectangular beam. The figures obtained for the modulus of transverse fracture showed that in the unheated condition the transparent material was considerably stronger than the opaque. When heated, it was found that a few hours at from 1,100°C. to 1,200°C. materially increased the strength of certain types of the opaque silica owing to an annealing action taking place. After more prolonged heating at 1,200°C. all types, both transparent and opaque, exhibited a loss of strength due to devitrification. This became much more serious and rapid at temperatures above 1,300°C. Heat treatment for four hours at 1,350 deg., for instance, may reduce the strength by from 40 per cent. to 60 per cent., according to the type of the material.

A microscopic examination in polarised light showed that the devitrification and loss of strength proceeded *pari passu*. The minute crystals of tridymite which are formed increase very greatly in numbers at the higher temperatures. They began to form chiefly at the surface of the specimens and from the walls of bubbles in the material. Other interesting phenomena affecting the strength of the material were also observed.

As is well known, the thermal coefficient of expansion of fused silica is very small, less than one-fortieth part of that of brass. In fact, it is smaller than that of any known substance excepting the best Invar. The difference in the coefficients of expansion of the transparent and opaque silica was determined over the range 0°C. to 900°C. The experiments showed that at no temperature in this range did the relative lengths of the two materials differ by more than 30-millionths of their length at room temperature. Assuming the total increase of length of a clear silica rod between 0°C. and

Digitized by Google

800° C. to be about 440-millionths of its original length, these experiments show that the increase of length of a similar rod of the opaque material does not differ from this by more than 7 per cent. The majority of the experiments gave differences of less than 5 per cent. Several interesting phenomena connected with the lagging of the expansion and contraction of the materials after heating and cooling were also observed. The experiments were carried out at the National Physical Laboratory at the request of the Thermal Syndicate, Ltd.

Prof. MAX BODENSTEIN, of Hanover, sent in a communication on

"Methods of Maintaining Constant High Temperatures."

Three general methods are in use.

1. By means of a vapour in equilibrium with its liquid. Suitable substances are only available for a moderate range of temperature, but a uniform temperature over a large volume is easily maintained. On the other hand, constancy of temperature over a long period cannot be relied upon.

2. A liquid heating bath controlled by a thermostat. For high temperatures the method is restricted by the difficulty in obtaining a suitable substance, although for moderate temperatures oil or paraffin in a suitably constructed bath are fairly satisfactory, and temperatures up to 350 deg. can be maintained within 0·05 deg. for several months if a sensitive gas regulator be employed.

3. For high temperatures air baths only can be employed. Tube furnaces heated electrically, either directly or by means of coils, are now exclusively used, but although a constant temperature is easily maintained, uniformity of temperature is more difficult of attainment. Usually the spiral heating coil is wound more closely at the ends of the tube, where the heat insulation should also be better, or additional resistances may be placed in front of the ends, and thus the heating of the middle portion of the tube is kept uniform. If there are any fluctuations in the current, it is necessary to employ a thermo-regulator. In the form recommended by the author the expansion of a confined volume of gas moves a column of mercury against a constant gas pressure. The motion of the mercury actuates, by means of a relay, a secondary current superimposed upon the primary heating current. Various modifications of the method are suggested, and it is stated that its use will render possible the maintenance of temperatures up to 1,500° C.

M. CHARLES FÉRY contributed to the discussion a short note on

"Stellar Pyrometry."

The temperatures of incandescent terrestrial bodies can be measured by reference to the laws of radiation, either the law of Stefan or the law of monochromatic radiations, but these cannot be applied in the case of stars, owing to the small amount of radiation. The author has therefore devised an instrument based on Weiss' displacement law, according to which temperature is measured by an appreciation of the colour tint of the star. In the instrument described, the colour of an image of the star is compared with that of a standard lamp whose tint can be varied. The pyrometer is standardised by reference to an electric furnace, an arc (3,500° C.) and the sun (6,500° C.).

In the course of the general discussion which followed the reading of the Papers—

Dr. T. M. LOWRY suggested the use of helium or argon in high-temperature gas thermometers instead of nitrogen.

Dr. J. A. HARKER agreed that a substitute would have to be found for nitrogen, which was not inactive in the electric furnace. Helium was impracticable, but he thought argon promising. The difficulty was a suitable containing material; they were trying to find one at the National Physical Laboratory.

Dr. ARTHUR DAY threw out the suggestion that tungsten might be found a possible material.

Prof. A. K. HUNTINGTON commented on the distinction which should be drawn between the diffusion of gases through metals, which depended on affinity, and through porcelain, which was merely a matter of porosity.

"The Central."—The current number of this journal is an "overseas" issue, though the editors point out that it is only a partial realisation of their hopes to publish a number entirely devoted to "Centralians" in India. Nevertheless, two of the articles do deal with Indian affairs, these being "Indian Industrial problems," by Mr. A. Chatterton, and "Life in India," by Mr. A. Marshall. In other articles Mr. C. S. Hainsworth describes the "Selina Cruz Port Works," and Mr. A. B. Jones the "Central Cordoba Extension Railway," which allows this system an independent entrance into Buenos Aires. Besides the illustrations in the articles there is an excellent photograph of Prof. M. O. Forster, F.R.S.

PREPARATION AND PROPERTIES OF THE HEUSLER ALLOYS.*

BY A. A. KNOWLTON.

Summary.—The method of preparing the alloys is first described. The magnetic examination shows the favourable effect of annealing at the upper limit of transformation. The transformation temperature depends upon the composition. Photographic examination shows the close dependence of the magnetic properties upon the crystalline structure.

Since the discovery by Heusler in 1903 that it is possible to prepare strongly ferro-magnetic alloys of the non-magnetic metals copper, manganese and aluminium, important papers concerning the properties of these alloys have been published by Heusler, Starck, Take, Gumlich, Guthe and Austin, McLennan, and others. The most important facts as developed by these investigators may be briefly summarised as follows:—(1) The magnetic permeability of the best specimens is about that of cast iron. (2) The permeability is often greatly increased by annealing for some time at a temperature a little above 100° C. At higher temperatures the alloys become non-magnetic and this transformation may be irreversible. (3) The most strongly magnetic alloys were found by Heusler and Starck to be those containing manganese and aluminium in atomic proportions, *i.e.*, in the ratio of two parts by weight of manganese to one of aluminium. Largely upon this ground it has been quite generally assumed that the copper plays no part in the alloy except as a solvent for a magnetic manganese-aluminium alloy, which would otherwise be too hard and brittle for experimental use. (4) Other trivalent metals as arsenic, antimony, or tin may be substituted for the aluminium, but the alloys thus obtained are much inferior to those containing aluminium. (5) Zahm and Schmidt have found a Hall effect in these alloys of the same sign as in iron, but larger than in any substance previously studied. (6) Ingersoll has found that these alloys do not show the Kerr effect. This is of special importance, both on account of the theoretical importance of the phenomenon itself and because it is the only way in which the magnetic properties of these alloys are strikingly different from those of iron.

As nearly all observers had found occasion to complain of the poor mechanical quality of their specimens, it seemed best at the outset to undertake such a study of their preparation as should, if possible, overcome this difficulty. The first stage of the preparation consisted in dissolving manganese in molten copper. On account of the great affinity of manganese for silicon a graphite crucible must be used, and it is even then impossible to employ any flux without causing the metal to eat rapidly into the crucible. To secure a uniform mixture the melt must be kept hot for several hours and stirred frequently—or the same result may be obtained with less loss by oxidation if the bath is cast and remelted several times. The materials used were ordinary electrolytic copper and, at first, chemically pure manganese. Later commercial manganese was used with apparently equally good results. To the copper-manganese alumi-nium in slightly more than the calculated amount was added, and the bath cast and remelted several times to ensure a uniform mixture. Stirring should be avoided during this part of the operation because of rapid oxidation of the aluminium. Even under the best conditions of working with small quantities of material the loss in this way is considerable and uncertain, so that the proportions by analysis may vary widely from those of mixing. After several remeltings the alloy was cast in graphite moulds made by boring a ⅝ in. hole in an arc furnace electrode. To provide for a uniform rate of cooling in all parts of the casting these moulds were heated before use to a temperature slightly above the melting point of the alloys, which was about 850° C. The very heavy slag which forms instantly over any exposed surface makes it essential that the metal be poured rapidly in an unbroken stream. The moulds were covered over with a layer of asbestos wool of such thickness as to allow the temperature to fall to 250° C. in about an hour. When this temperature was reached, as indicated by a thermocouple, the casting was quenched by immersion in cold water. Specimens prepared in this way were of excellent mechanical quality, free from flaws and blow-holes and, in many cases, malleable to a considerable degree. The magnetic test appears to indicate that a somewhat slower rate of cooling and a slightly higher temperature of quenching might have been advantageous. Fourteen specimens were selected at random for examination. These were wet ground with emery to a uniform diameter of 6 mm. and tested as hereafter described. The chemical composition and density (which ranged from 6·72 to 7·17) of each specimen is given by the author. In general the density was found to increase slightly on annealing at 120° C. This increase never exceeded ½ of 1 per cent. although it appeared to take place in all cases.

* Abstract of an article in the "Physical Review."

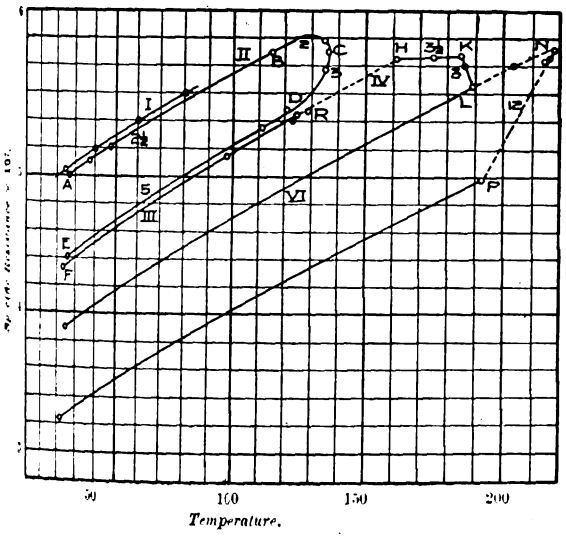
Electrical Resistance and Temperature Coefficient of Resistance.—For measuring the resistance a Thomson double bridge was used. The external field was constant and equal to 80 lines/cm.^{2} during these tests.

The variation in the value of the specific resistance (σ) for different specimens was larger than can be accounted for by differences in composition. Later work indicates that a slower rate of cooling would have given more uniform results. The variation of σ with temperature, shown in the figure, refers to only one specimen, but it is typical of what happens in every case. The curves are straight lines differing from those for a pure metal only in slope, and in that at certain temperatures the resistance undergoes a permanent decrease with time, a process of artificial ageing frequently met in alloys. The numbers given in the diagram indicate the time which elapsed between the lettered readings; *e.g.*, in curve II. the reading at C was taken two hours after that at B. The microscopic examination which was carried on in connection with this part of the work showed that each decrease in resistivity accompanied an improvement in crystalline structure, and that any treatment, such as quenching from a comparatively high temperature, which impaired the crystallisation was accompanied by a corresponding increase in resistivity. There was no indication that the resistance depended at all upon the kind of crystals. The temperature coefficient (α) which was originally very low and lowest for the specimens of highest resistivity (varying from $9{\cdot}1\times10^{-4}$ to $27{\cdot}3\times10^{-4}$) increased as the resistance at zero decreased and in nearly the same ratio, as is shown by the fact that the successive curves are parallel. It will be noticed that after five hours at 140 deg. the succeeding heatings represented by III. and IV. (both of which began at 28 deg.) produced no effect, but that above 160 deg. a second rapid decrease in resistivity took place until a second condition of stability was reached, which persisted until the



temperature was raised above 225 deg. In some later work it has been found that these three temperatures are important transition points for many specimens. The only way in which these alloys are different from many others in respect to their conductivity is in the degree of their sensibility to annealing processes, and this is altogether due to the ease with which their crystalline structure undergoes modification.

Relation of Magnetic Quality to Crystalline Structure.—Several of the specimens were subjected to extensive cycles of heating, magnetic measurements being made before and after each cycle, and at such other temperatures as seemed desirable. Before and after each cycle one end of the specimen was polished and etched with a mixture of hydrochloric acid and ferric chloride. This mixture was adopted after experiments with many etching agents because it was found to give more uniform results than any other, and also because the colouring action of the ferric chloride greatly increased the contrast between the different crystals. An outline of the treatment to which a single specimen was subjected and the results obtained are given in the Paper. The total time of annealing in this case was somewhat more than 100 hours, and the value of the magnetisation reached varied from about 400 C.G.S. units to zero, with corresponding variations in crystalline structure, as is shown in a set of microphotographs in the Paper.

A comparison of the value of the intensity of magnetisation I, with its original value, shows an increase from 212 to 298 for the same field strength. This increase took place at ordinary temperatures during a period of 16 months. Heating to temperatures up to 160 deg. apparently completed in something less than 20 hours the transformation which had been going on slowly at room temperatures. Heating at 225 deg. for five hours caused a 25 per cent. decrease in the value of I, while two hours at 290 deg. restored the specimen nearly to its best condition. Subsequent heatings at temperatures below 225 deg. produced no effect. Even a short time at 225 deg., however, produced a marked change, and the loss of magnetic quality continued on further heating at 225 deg. and 250 deg. Partial recovery again followed heating to 300 deg. Nine and one-half hours between 225 deg. and 250 deg. left the specimen very poor magnetically with the expected recovery at 300 deg. or slightly above. After this heating to 350 deg. it was noticed that the alloy reacted to the etching agent very differently from its previous behaviour. Up to this point there had been no tendency to deposit copper, even when the etching was continued for from five to eight minutes, but on attempting to etch following this heating a coating of copper so thick as entirely to conceal the structure was deposited in less than half a minute. This, of course, indicates a breaking-up of some of the crystals. Chilling from this temperature left the alloy non-magnetic, and it was not found possible to render it magnetic again by any thermal treatment, although after some months at ordinary temperatures it was found to have become appreciably magnetic again.

These results are in good accord with those of Asteroth who states that he found it possible to control hysteresis losses by the rate at which his specimens were cooled through the transformation temperature. The writer's interpretation of the phenomena is, however, somewhat different. Transformation from the magnetic to the non-magnetic state takes place over a range of about 50 deg., the lower limit for this particular specimen being 225 deg., where the loss of magnetic quality begins to take place rapidly, and the upper limit being 275 deg., where the specimen is totally non-magnetic. Annealing at the lower limit leaves the alloy very hard and with a low maximum induction, while annealing at the upper limit, followed by moderately rapid cooling, softens the specimen and increases the maximum induction. This was found to be the case with all specimens examined.

So far as the permanent changes that take place on heating are concerned, they may be explained if we assume that the magnetic properties belong to molecular groups which are constituents of a certain type of crystals that form at temperatures in the neighbourhood of 300 deg. and are stable at ordinary temperatures, but pass through a meta-stable condition between 225 deg. and 275 deg., while the non-magnetic crystals, which constitute the stable form within this range, are meta-stable both at 300 deg. and at room temperatures. An examination of the micro-photographs appears to verify this assumption.

The micro-photographic examination which was carried on in connection with the magnetic testing showed that the alloys contain crystalline masses of three distinct sorts. Of the three sorts of crystalline masses (white, dark grey and black) those which are unaffected by the reagent, and consequently appear white in the prints, are by far the most striking and show the widest range of variation. The area of the photograph covered by these crystals is large in all cases where the specimen was highly magnetic and decreases with loss of magnetic quality. So marked was the relation between structure and magnetic quality that after some experience it was found possible to make a fairly accurate estimate of the value of I at saturation from a visual examination of the structure. The areas covered by the white crystals on a number of photographs were estimated by means of squared paper, and within the limits of error (which are naturally large) these areas appear to be proportional to the values of I at saturation.

Although the differences in chemical composition did not appear sufficient to account for the observed differences in the transformation temperature, no other cause could be assigned, since in no case did the heat treatment appear to produce any change in this regard. An attempt to reproduce the alloys of low transformation temperature by making specimens having a high ratio of copper to manganese (Cu 72, Mn 18, Al 10) was successful. This result is in line with the work of Ross and Gray in indicating that the copper plays a part of much greater importance than a mere solvent.

Since the white crystals are always present in magnetic specimens and are never found in specimens which are not, under proper conditions, magnetic, and since there seems to be a simple relation between the quantity of crystals of this kind and the magnetic quality, it seems fair to assume that they contain the magnetic constituents of the alloy. Attempts to isolate these crystals were unsuccessful. A surprising feature is the apparently slight difference between the magnetic and non-magnetic states as indicated by the fact that careful experiments with an apparatus of great sensitiveness failed to show positive evidence of any evolution of heat on passing through the transformation range.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" *commence in April and October.*

(This charge includes all the numerous Supplements.)

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 8s 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s; Europe, 2s; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the 1911 Edition sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription, 5s., post free.

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Now Ready.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d. *Now Ready.*

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms only, bound strong cloth. Price 5s. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY. AN ELEMENTARY TREATISE. FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. C. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. [Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton. M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated. Prize 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free. [Price 3s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. Being Vol. I. of a Complete Manual of Lifting and Hauling Machinery. *Ready shortly*, price 25s. nett.

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *Nearly ready.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

SPECIAL NOTICE FOR CORONATION WEEK.

"THE ELECTRICIAN" will be published on Saturday instead of on Friday in Coronation Week.

As it will be necessary for the Publisher to have the paper practically completed by Wednesday night (Friday being a holiday in London), Contributors and Advertisers will please send their copy for Contributions and for new Advertisements and changes in running Advertisements not later than first post Wednesday in Coronation Week.

THE CORROSION OF IRON AND STEEL.

The annual London meetings of the Iron and Steel Institute appeal in point of interest not only to the iron founder and to the metallurgist, but to the engineering community at large, which owes so many of its achievements to the improved products from foundries and rolling mills. Every year iron and steel enter more and more into our daily lives, and user and producer find their identity of interest to be more intimate. From the user's point of view, perhaps, the outstanding feature of general interest in the recent meeting of the Institute lay in the three Papers dealing directly with corrosion. As the annual outlay of the world on account of liability to corrosion now reaches an enormous sum, not only through the cost of preventive measures, but through the actual loss of metal in cases where preventive measures cannot be applied, to say nothing of accidents arising through corrosion, we make no apology for referring to the main points of these Papers.

At the present time the mechanism of corrosion is warmly debated by two schools, which have been respectively labelled the chemical and the electrolytic. The former regards all corrosion as primarily a matter of oxidation produced through the action of acids upon the metal. The latter regards corrosion as in the main due to local galvanic

Digitized by Google

action between different metallic impurities in the presence of a suitable electrolyte.

Now of the three Papers presented, that by Messrs. J. Newton Friend and Joseph H. Brown upon "The Action of Aqueous Solutions of Single and Mixed Electrolytes upon Iron" must be regarded, despite the use of the word "electrolyte" in its title, as identified mainly with the chemical school. The experiments were all conducted upon what is nominally a single metal—namely, "relatively pure iron." (It is to be regretted that the authors did not give an analysis of this.) Plates of this iron were immersed in various saline solutions, with the result that in each case the corrosion was found to be a minimum for dense solutions. Employing solutions of different salts containing 0·1 gramme of potassium bichromate per litre, it was found that corrosion was retarded and that potassium chromate gave even better results. We have spoken of "relatively pure iron" as nominally a single metal, but pure iron, in the sense that electrolytic copper is pure, is not known to the metallurgist. Commercial iron and steel are relatively impure, and therefore the electrolytic school must regard this Paper as academically valuable rather than as conclusively practical.

The second Paper, by Mr. John W. Cobb, on "The Influence of Impurities on the Corrosion of Iron," represents a research conducted wholly from the point of view of the electrolytic school. The Paper covers observations of the colour reactions observed in the Walker and Cushman "ferroxyl" cell between iron and the sulphides, phosphides and silicates. This very sensitive device indicates by respective blue and pink colouration whether metals, or portions of them, are electro-positive or electro-negative to other metals or to parts of the same metallic plate. Mr. Cobb clearly shows that in the ferroxyl solutions iron is electro-positive to slag—that is to say, that a current will flow (if the conditions of a closed electrical circuit are secured) from the iron to the slag, and the iron tend to pass into solution. It must, however, be remembered by all who study this interesting and valuable Paper in detail that it does not necessarily follow that what is true of the ferroxyl cell is true of all conditions in which other electrolytes occur in contact with dissimilar metals. Metals which are electro-positive to other metals in one solution are known to be electro-negative in another solution. Also, too, the method followed by Mr. Cobb in the measurement of the E.M.F. between dissimilar metals by using a galvanometer calibrated as a millivoltmeter only affords relative measurements which are not scientifically comparable with those obtained by other observers using either a millivoltmeter of different internal resistance or electrodes of different area, or a cell with the same electrolyte but with a different length of path between the electrodes. The only really reliable method is the potentiometer.

The third Paper, by Mr. Percy Longmuir, on "The Corrosion of Metals," is at once wide in its scope, and distinguished in many of its conclusions. It commences with the action of tomato juice on the domestic table knife, it discusses variations in the composition of the atmosphere and rain water in various districts, as well as that of the soot in domestic and locomotive chimneys and in tunnels, and concludes with some striking work on the relation between rail failure and corrosion. Mr. Longmuir's Paper should be read in detail by those interested. On the whole he considers that "the balance of evidence appears to be in favour of the electrolytic theory." But "purity of composition alone is not the clue to immunity from, or retardation of corrosion." There are "numberless cases in which composition of metal has been of considerably less moment than its environment."

Mr. Longmuir regards sulphur in soot and in the atmosphere as a most important factor, and records many cases of sulphur in excessive quantity in rust and in tunnel water. His chief contention is that the problem of corrosion does not lie in the amount of metal lost by rust or decay, but in the influence exerted on the metal remaining intact and apparently unaffected. Deterioration is found which is not explained by mere loss in weight or change in the ordinary condition of the metal. This theory is illustrated by the case of a steel rail from a damp tunnel. No rail is absolutely homogeneous, and this is well shown by a case of a normal rail from which tensile test pieces cut from different parts of the cross section, which had been mapped out, showed large variations as compared with a rail from a tunnel. From these results the author deduces that the rail from the tunnel had been rendered decidedly brittle by its environment and service conditions; and, instancing the well-known parallel of acid cleaning causing brittleness in wire, he urges that under working conditions "the degree of acidity is immaterial provided the time of attack is sufficiently prolonged." The railway engineer will naturally demand from metallurgists more evidence in support of this seemingly well-founded theory. Apart from railway interests in this section of the subject, the general concern about corrosion is very deep.

This is not the occasion on which to discuss protective coatings. It must be remembered that cases are inevitable in which protective coatings either cannot be applied, or, if applied, are difficult of uniform maintenance. It is right, therefore, that the metallurgist, the chemist, and the physicist should continue to concern themselves with the study both of the mechanism of corrosion and of its effects. From their efforts we may hope to obtain metals as superior in their resistance to corrosion to those now in everyday use as a good mild-steel casting is superior to good cast iron.

REVIEWS.

(Copies of the undermentioned works can be had from The Electrician Office, post free, on receipt of published price, adding 3d. for books published under 3s. Add 10 per cent. for abroad or for foreign books.)

Diagram for the Easy Calculation of Shaft or Beam Deflections.

By R. Livingstone. (London: "The Electrician" Printing & Publishing Co.) 2s. 6d. net. Postage in tube 4d. extra.

This sheet has two diagrams, of which the former consists of a series of curves plotted on rectangular co-ordinates so that the lengths of a beam supported at each end form one side, and certain coefficients "k" are plotted as ordinates with this side as base.

It can be shown that a concentrated load so placed as to divide a beam into segments "a" and "b" produces a deflection "δ" at a distance, x, from one end given by the expression

$$\delta = \frac{Wbx}{EI(a+b)} \cdot \frac{x^2 - a^2 - 2ab}{6} \cdot L^3 = k \cdot \frac{WL^3}{EI}.$$

(Morley's "Strength of Materials," p. 161.)

Digitized by Google

The values of "k" obtained in this way and plotted as described enable the deflection for a series of loads to be obtained by summing the values of "k" for each load. The second diagram for distributed loads is a single curve connecting the deflection at a point with the position of this latter on the beam.

A brief description of the method, including an example of a calculation, is printed on the diagram, and this shows very clearly that an otherwise laborious calculation can be performed with ease and accuracy. E. G. Coker.

Several questions have come to hand regarding the accuracy of Mr. Livingstone's, recently issued diagram to which the above review refers. One of these questions was: "Could you guarantee a Livingstone diagram to give the deflection accurately to 0·0001 in the case of shafts about 6 ft. span and, say, four concentrated loads?"

The following reply by Mr. Livingstone will be of general interest:—

1st. As the total deflection at any point is the *sum* of the deflections at that point, due to the individual loads, the percentage error due to inaccurate drawing of the curve will be less for a number of loads than for a single load, since such errors tend to cancel each other.

2nd. The accuracy of drawing of the curve is good, as the following comparison between carefully integrated and calculated values of "K" and the values read from the curves will show.

Deflection considered at 0·3 of the Span.

Position of load.	Actual value of "K."	K from curve.	Error.
0·1	0·00583	0·00580	0·57 of 1%
0·2	0·01096	0·01100	0·305 of 1%
0·3	0·01470	0·01470	0
0·4	0·01650	0·01650	0
0·5	0·01650	0·01650	0
0·6	0·01500	0·01500	0
0·7	0·01230	0·01230	0
0·8	0·0087	0·00870	0
0·9	0·0045	0·00445	1·1%

3rd. From the above table we may assume that the average error is much less than 1 per cent., and as the value of the deflection in a 6 ft. span would be about 0·020 in., an error of $\frac{1}{2}$ of 1 per cent. would be an error in value of 0·0001, which is what your correspondent wishes.

4th. In actual practice such accuracy is not required. The most accurate test is a case of three or four bearing spans, where the deflection at a point is found from the difference between the vertical loads and upward reactions. In such cases an error exceeding 5 per cent. is not admissible.

5th. The preceding is based on the assumption that $\frac{L^3}{E \cdot I}$ is accurately determined. Now E may vary between 28×10^6 and 30×10^6, which is a possible error of 7 per cent.

6th. In conclusion, (*a*) we cannot guarantee that the error will be 0·0001 in., as the whole deflection might be too large to make this appreciable percentage of the total. (*b*) But with average deflections of, say, 0·01 in. to 0·02 in. we can guarantee the accuracy of the deflections calculated from the curves within 0·0001 in. when $\frac{L^3}{E \cdot I}$ is correctly obtained and the shaft is homogeneous. (*c*) Or we can guarantee the accuracy of the values of the constants within 1 per cent.

Practical Telephony. By G. Bell and S. Wilson. 5th edition. (London: S. Rentell & Co.) Pp. xiv. + 309. 3s. 6d. net.

This book is written to meet the requirements of students preparing for the examinations of the City and Guilds of London Institute and the Post Office departmental examinations. It deals for the greater part with the systems and methods adopted by the British Post Office, and only somewhat sparingly with the practice of other administrations.

In the first half of the book where they deal with exchange systems, signalling apparatus, instruments and circuits, &c., the authors seem to have been on unfamiliar ground, and in not a few instances "at sea" altogether, as for example on page 83 where the operator's transmitter, shown in Fig. 81, is referred to as a "supplemental resistance of 55 ohms," and on page 104 where the main ringing machine shown in Fig. 101 in connection with the night bell circuit is described as "a generator for the operator's use when the motor generator is not running." This part of the book contains an extraordinary number of inaccuracies, loosely worded descriptions, and discrepancies between diagrams and letterpress, which render it of little value to students, who are frequently not in a position to detect such errors.

Although there is no direct reference to the Daniell cell in the book, the authors seem to have experienced some difficulty in abandoning what has evidently been an old friend, and we find the positive pole of subscribers' batteries frequently referred to as the "copper" pole, and the negative pole of the main battery in a CB exchange as the "zinc" pole.

Although numerous diagrams of circuits are given, none of them carry titles, and to find out what circuit is illustrated one is compelled to search about in the text for the corresponding figure number. Reference to diagrams would be much facilitated if each one bore a title, and, in the same way the text would be considerably improved by a more liberal use of sub-headings.

In view of the great importance of the subject one would expect to find in a modern work at least one chapter devoted to traffic matters, and it is disappointing to find that in the present volume the subject is practically ignored.

The last half of the book deals with methods of testing and localising faults, overhead construction and telephone cables, the latter portion including a description of the loaded cable recently laid across the channel at Dover. These chapters form, perhaps, the best part of the book.

The final chapter contains the syllabus upon which the City and Guilds examination papers are based, and the questions set during the last seven years in both the Ordinary and Honours Grades. These will be useful to prospective candidates. H. S. T.

Logarithms for Beginners. By C. N. Pickworth. (London: Whittaker & Co.) 3rd edition. Pp. 42. 1s.

We do not appear to have had the pleasure of reviewing former editions of this book, and it is therefore rather difficu for us to tell exactly how it has been improved, or whether it ha been improved at all. From the preface to the first edition i appears that its purpose is to give a more detailed and prac tical explanation of logarithms and their various application than is to be found in text books on algebra and trigonometry From this point of view the book is well done, though we can not subscribe to the author's argument that it is necessar There is, however, evidently a demand for the book, since it ha reached a third edition.

THE PRINCIPLE OF THE STATIC BALANCER.

BY C. C. HAWKINS.

Summary.—The theory of the static balancer is here developed simple lines by the superposition of the component currents. An actu case is worked out numerically.

The general idea of a static balancer as a means of obtaini a point of connection for the middle wire of a three-w system with a single generating dynamo is not difficult follow. If two or more slip-rings are connected at proj intervals to the armature winding of a continuous-curre dynamo, then from each brush pressing on a slip-ring a le can be taken to one end of a coil forming part of a stationa inductive resistance or "static balancer" which has as ma limbs or coils as there are slip-rings; the other end of each c is connected to a common junction, and this forms a cen point to which the middle wire of the three-wire network m be attached when only a single dynamo is feeding the outs Yet though this general idea is readily grasped, a thorou

Digitized by Google

understanding of the inner working of the apparatus requires that its fundamental principles should be very clearly understood. It is, therefore, proposed here to examine these principles, beginning from an elementary standpoint.

The static balancer is essentially and fundamentally a *choking coil*, and the lower its ohmic resistance, the more nearly for a given difference of resistance on the two sides of the network and a given armature resistance is the potential of the third wire brought to a value midway between the potentials of the outers. Each limb or coil of the balancer is to be regarded as a "phase," so that there are as many phases as there are slip-rings. What is often called the single-phase balancer is, therefore, strictly speaking, two-phase.* If the one coil, A, carries current, say, towards the centre of the balancer, and the same current continues onwards, then the other coil, B, even though it is merely a continuation of the same winding, is carrying this current away from the centre and so forms the second phase, displaced by 180 electrical degrees relatively to A. The sign of the current in any coil is thus to be regarded as fixed by its direction relatively to the central or junction point, inwards towards it being regarded as negative, and outwards, away from it, as positive. If the above two-phase balancer has its two coils on a common core, its actual construction closely resembles that of a one-to-one transformer with its primary and secondary coils, preferably

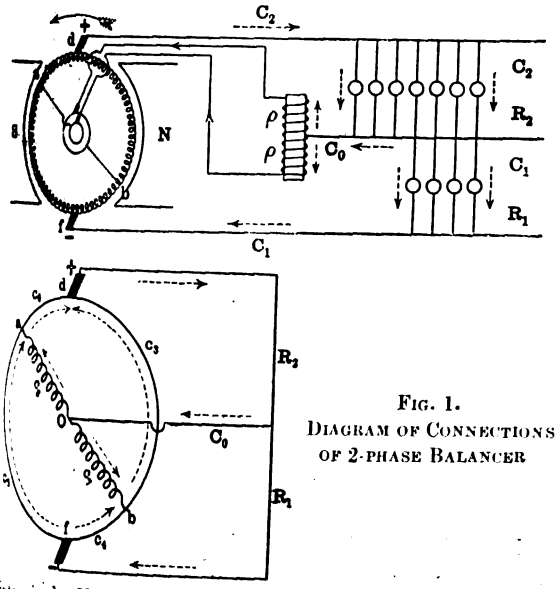

FIG. 1.
DIAGRAM OF CONNECTIONS OF 2-PHASE BALANCER

intermixed. Yet if the coils of the static balancer were not wound on a common magnetic core but were kept entirely distinct, although the arrangement would not for other reasons be nearly so good, its essential action would remain unimpaired; the fluxes of the phases do not, therefore, necessarily have a common magnetic circuit, which suffices to prove that the function of the balancer is that of a choking coil and not that of a transformer.

Taking the simplest case of two slip-rings and two coils or phases, the connections are as shown in Fig. 1. Below is shown diagrammatically the various portions of the system of armature, network and balancer, lettered with corresponding symbols to agree with the upper portion of the figure.

The resistances and impressed E.M.F.'s are given in a still more simple form in Fig. 2. Each leg of the balancer has a resistance of ρ ohms, and except when the balancer tappings pass the brushes, the balancer divides each half of the armature into two portions, *fb*, *bd*, which are fractions q and $(1-q)$ of the length between *f* and *d*. If R_a = the joint resistance of all paths in the armature winding from + to − brushes, one-half of the armature (which may itself consist of several parallel paths) will have a resistance of $2R_a$ ohms, and the resistance of the portions *fb* and *bd* will be respectively $2R_a.q$ and $2R_a.(1-q)$.†

* A true single-phase arrangement is theoretically possible, but gives a strongly pulsating middle wire current.

† The same symbols are here used as in the writer's original communication on the "Theory of the Static Balancer," Journal I.E.E., Vol. XLV., p. 704, for the convenience of any reader who might wish to pursue the matter further.

If E_3, E_4, E_5, E_6 are the instantaneous E.M.F.'s induced in each of the four portions into which the armature is divided, the two E.M.F.'s on one and the same side of the balancer act differentially against each other, and their varying difference, *i.e.*, E_3-E_6 or E_5-E_4, yields an E.M.F. alternating with respect to the balancer, and having a frequency $f=\frac{pN}{60}$, equal to that of the machine, where p is the number of pairs of poles and N is the number of revolutions per minute.

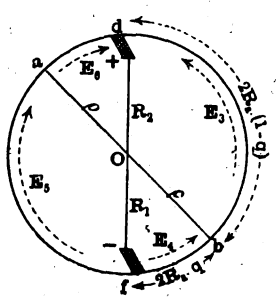

FIG. 2.—SIMPLIFIED FORM.

In the first place, let the third wire be completely disconnected from the centre of the balancer, and also let the network be balanced so that $R_1=R_2=R$. The alternating E.M.F. above described causes an alternating current, i, to flow through the two limbs of the balancer in series, and considered by itself this current would divide equally at the points *a* and *b*, $i/2$ flowing through each of the halves into which the armature is divided (Fig. 3*a*). Upon this distribution of current must be superposed the direct-current balanced system of Fig. 3*b*, so that when the two are added together, having regard to their directions in the several portions, Fig. 3*c* is obtained. It will be seen that the armature currents are divided (except at the moment when the balancer tappings pass the brushes) into *two similar pairs*, viz.,

$$i_2=i_5=\frac{C_b}{2}+\frac{i}{2},$$

and

$$i_4=i_6=\frac{C_b}{2}-\frac{i}{2},$$

just as in a single phase rotary converter. The iron in the trailing portions of the poles being influenced by one pair of circuits and so also that in the leading sides by the other pair,

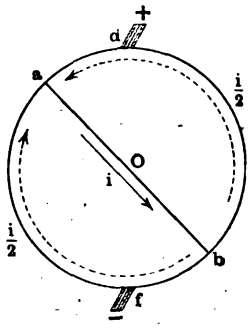

FIG. 3*a*.

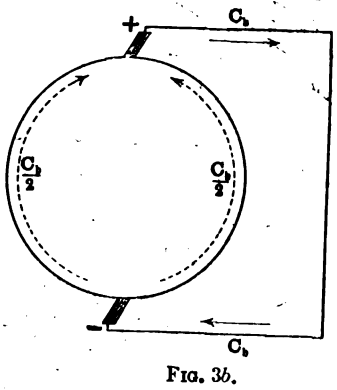

FIG. 3*b*.

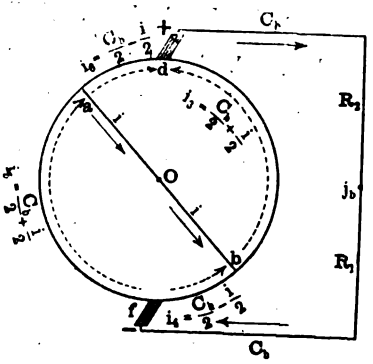

FIG. 3*c*.—THE SYSTEM WITH THIRD WIRE REMOVED.

the arrangement is so far symmetrical, and in relation to the induced and self-induced E.M.F.'s we are also correct in taking at each moment $E_3=E_5$, $E_4=E_6$, $L_3=L_5$, and $L_4=L_6$, where L_3, L_4, &c., are the instantaneous inductances of the several portions.

The principle of all such superpositions of current is the same, viz., that the actual total induced E.M.F.'s may be split up into any components that we please, so long as their

Digitized by Google

algebraic sum is correct, but that if this is done, each component E.M.F. will always produce its own corresponding currents throughout the whole system, and the algebraic sum of these in any portion will yield the actual current in that portion.

But, now, if we wish to divide the actual distribution of currents into the above alternating and direct-current sets, the proportions into which the total E.M.F. is divided must be correctly taken in order to secure the required result.

One might at first sight suppose that it would only be necessary to take a direct current of value in the external circuit,

$$C = \frac{E_a}{2R + R_x}$$

(the shunt current being for simplicity neglected), and upon it to superpose an alternating current of value in the balancer,

$$i = \frac{E_3 - E_4 - \frac{1}{2}(L_3 + L_4)\frac{di}{dt} - 2L\frac{di}{dt}}{2\rho + R_a},$$

where L is the inductance of one limb of the balancer. But such a superposition would be incorrect, since the two component E.M.F.'s which must be used are in reality dependent upon one another. The former expression would hold for the instant when $q = \frac{1}{2}$, and also when $i = 0$ (*i.e.*, for the instant when the alternating current is passing through its zero value), but not at any other moments; the latter expression only when $q = \frac{1}{2}$ or when $C = 0$, the last alternative being no-load when only the alternating-current exists.

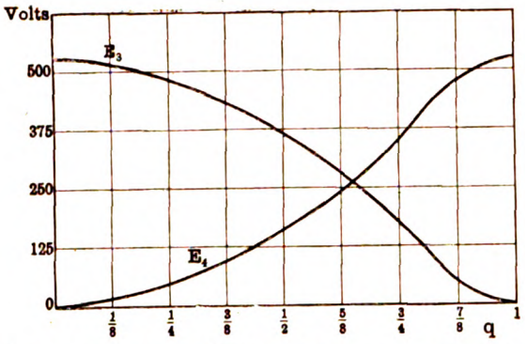

FIG. 4.—RISE AND FALL OF E.M.F. IN THE TWO PARTS OF THE ARMATURE.

To obtain the true direct current component C_b, the total impressed E.M.F. E_a must be reduced by the difference between the alternating-current ohmic losses in the two parts of the armature, *i.e.*, by $\frac{i}{2}\cdot 2R_a(1-q) - \frac{i}{2}\cdot 2R_a q = iR_a(1-2q)$, and also by the difference between the self-induced E.M.F.'s in the the two portions, *i.e.*, by $L_3\frac{di_3}{dt} - L_4\frac{di_4}{dt}$. Similarly, the whole of the differential E.M.F. $E_3 - E_4$ is not available as an impressed E.M.F. to cause an alternating current, but only this amount less the difference between the direct-current losses in the two parts of the armature or $C_b \cdot R_a(1-2q)$.

The true expressions for the instantaneous values of C_b and i need not here be examined, so long as the consequences of their interaction are clearly understood. The important fact to be remembered is that by the connection of the balancer across the armature, C_b is rendered slightly pulsating, and only coincides in value with C at the particular moment when $q = \frac{1}{2}$, or the tappings stand at right angles to the brushes. So also the instantaneous terminal voltage, v_{eb} is rendered pulsating about a mean value. Thus if the letters *a*, *b*, *d*, *f* (Fig. 3*c*) also represent the actual potentials at these points, the difference of potential between the brushes or v_{eb} is

$$d - f = E_3 + E_4 - \left(\frac{C_b}{2} + \frac{i}{2}\right)2R_a(1-q) - \left(\frac{C_b}{2} - \frac{i}{2}\right)2R_a q - L_3\frac{di_3}{dt} + L_4\frac{di_4}{dt},$$

$$i.e., \quad v_{eb} = E_a - C_b \cdot R_a - iR_a(1-2q) - \left(L_3\frac{di_3}{dt} - L_4\frac{di_4}{dt}\right) \quad . \quad (1)$$

By the varying values of the last two terms v_{eb} is caused to pulsate slightly, whether C_b have any value or not, *i.e.*, whether on no-load or full load. When $q = \frac{1}{2}$, $L_3 = L_4$ and $\frac{di_3}{dt} = \frac{di_4}{dt}$; further, whatever alternating current may then be flowing raises the ohmic drop in one quadrant as much as it lessens it in another quadrant, so that neither of the two last terms affects the terminal voltage, and at this moment we return to $v_{eb} = E_a - CR_a$, as if there were no balancer.

When $q = 0$, $\frac{di_3}{dt}$ is positive and acts on L_3, which now is the inductance of one half of the armature $= L_a$, while i is positive. Hence v_{eb} is reduced to a lower value $= E_a - C_b R_a - iR_a - L_a\frac{di_3}{dt}$, and this same value also holds when $q = 1$, since, then, both i and $(1-2q)$ have changed sign, while $\frac{di_4}{dt}$ of negative sign acts on $-L_4$ in equation (1).

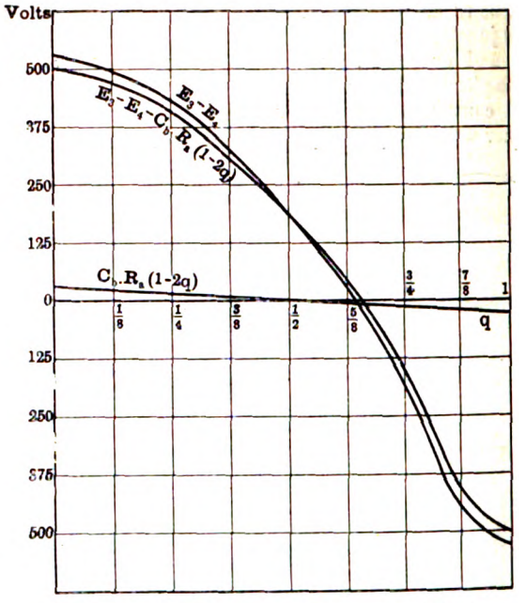

FIG. 5.—THE TRUE ALTERNATING E.M.F

In the intermediate stages there would have to be considere not only the changes of $\frac{di_3}{dt}$ and $\frac{di_4}{dt}$, but also the varying pr portions of L_3 and L_4.

But the whole effect from the self-induced E.M.F.'s in th armature is small as compared with that from the inductanc of the balancer itself. It only needs to be emphasised that b reason of the high inductance that is given to the balancer, th phase of the alternating current through it lags very greatl behind the impressed E.M.F.; the latter is a maximum whe $q = 0$ or 1, *i.e.*, when the tappings pass the brushes, and th current is then but little removed from zero, so that it is ver far from changing its direction when $q = \frac{1}{2}$. On external n load, when the tappings pass the centre of the poles and $q =$ $E_3 = E_4$, and the impressed E.M.F. is zero, but under loa owing to the field being distorted forwards by armature r action (Fig. 4), E_3 does not become $= E_4$ until much later, a this delaying action is also reinforced slightly by the fact th the impressed alternating E.M.F. is not simply $E_3 - E_4$, b $E_3 - E_4 - C_b \cdot R_a(1-2q)$, as shown in Fig. 5. The alternati current will then be nearly at its maximum and $\frac{di}{dt} = 0$, p haps later than $q = \frac{1}{2}$. The two half-waves of E.M.F. will dissimilar, and the current-waves owing to the presence of ir will be further distorted, but beyond the above general stat ment their exact shape need not further be more particular considered.

The network being so far assumed to be balanced, the sa current flows in series through the two limbs of the balanc and since these are assumed to be similar in both winding a magnetic data, even if they are on separate cores, it is evid

Digitized by Google

that the potential of the centre point of the balancer is at every moment exactly midway between the potentials of the points a and b, or is equal to $\frac{a+b}{2}$. Further, from the symmetrical distribution of the currents the potential of the brush d is always as much above that of point a as the potential of brush f is below that of point b. For example, by Fig. 3c,

$$d = a + E_3 - i_3 . 2R_a q + L_3 \frac{di_3}{dt},$$

$$f = b - E_4 + i_4 . 2R_a q - L_4 \frac{di_4}{dt},$$

and, therefore, since $E_4 = E_3$, $i_4 = i_3$ and $L_4 \frac{di_4}{dt} = L_3 \frac{di_3}{dt}$, $d + f = a + b$.

Or the potential of brush d might have been obtained from that of b as a starting point, and the potential of brush f from that of a with the same result as above.

Thus the network being balanced, the midway value between d and f is the same as the midway value between a and b. The potential of the middle of the network is also $\frac{d+f}{2}$, so that if the third wire is connected to the centre of the balancer, no current passes and the entire system is unchanged.

Let the load on the two sides of the network now be unbalanced, the effective resistances (whether from lamps or motors) on the two sides being R_1 and R_2, and R_1 being the resistance of the negative side. If the balancer were absent, the potential of the middle wire instead of being $\frac{d+f}{2}$ would be $\frac{d+f}{2} + J_0$, or the initial divergence of the centre potential from its true value midway between those of the brushes is $J = (R_1 - R_2)\frac{C}{2}$, *i.e.*,

$$J_0 = \frac{R_1 - R_2}{R_1 + R_2} \cdot \frac{V_e}{2} = \frac{R_1 - R_2}{2} \cdot \frac{E_a}{R_1 + R_2 + R_a} \quad . \quad . \quad . \quad (2)$$

where V_e is the initial terminal voltage.

The third-wire potential is thus above the mean, or J_0 is *positive*, when $R_1 > R_2$, or the *positive* side is the *more heavily loaded* and has the lower resistance.

Take the case of a dynamo of normal output 250 kw. at 500 volts; let $R_a = 0{\cdot}05$ ohm, and the induced E.M.F. of the armature be $E_a = 525$ volts. When the dynamo is well loaded, $R_1 + R_2$ must not be very far different from the balanced resistance which would give full load, *i.e.*, in our case 1 ohm. Let it be assumed that R_1 on the negative side is 0·55 ohm, and R_2 on the positive side 0·45 ohm. Then without any balancer, the output would be 500 amperes and 500 volts at the terminals, the latter being divided between the two sides of the network in the proportion of 275 volts on the negative side to 225 volts on the positive side, or

$$J_0 = \frac{R_1 - R_2}{R_1 + R_2} \cdot \frac{V_e}{2} = \frac{0{\cdot}1}{1} \cdot 250 = 25 \text{ volts},$$

i.e., on either side an initial divergence from the mean of 25 volts = 10 per cent. above or below the correct amount.

Now, let the balancer be joined across the armature so that an alternating current flows through it, but let the middle wire be still left unconnected to the centre of the balancer. As before, the direct current flowing through the two sides of the network in series, *i.e.*,

$$C_b = \frac{v_{eb}}{R_1 + R_2}$$

is rendered pulsating, and the new initial divergence, like v_{eb}, is also a pulsating quantity. Its instantaneous value is

$$j_b = (R_1 - R_2)\frac{C_b}{2} = \frac{R_1 - R_2}{R_1 + R_2} \cdot \frac{v_{eb}}{2} \quad . \quad . \quad . \quad . \quad (3)$$

which only becomes identical with J_0 at the particular moment when C_b becomes identical with C, *i.e.*, when $q = \frac{1}{2}$.

But the centre point of the balancer would always be at every moment at its true midway value, $\frac{d+f}{2}$. The consequence, therefore, of connecting the third wire to the centre must be an increased current on the side of the network of lower resistance and a decreased current on the other side, *i.e.*, a flow of an out-of-balance current through the middle wire of value $C_0 = C_2 - C_1$, and a consequent re-adjustment of the potentials so that j_b falls to some lower value j_0, and the voltages on the two sides of the network are more nearly equalised.

It remains, then, to examine the redistribution of potentials which results when the third wire is connected, and in the first place to consider in what way the magnetic conditions of the armature will be altered. It will be found that as soon as the middle wire is connected, and the out-of-balance components flow, the armature currents c_3, c_4, c_5, c_6, are no longer divisible into similar pairs, but are rendered *all dissimilar* except at certain instants. Yet, in spite of this, *in the drum armature*, since the windings carrying c_2 and c_5 are situated side by side, and so also those carrying c_1 and c_6, the iron of the armature and pole-pieces is similarly affected in parts 3 and 5, and also in 4 and 6, so that

$$E_3 = E_5, \; E_4 = E_6,$$
$$L_3 = L_5, \; L_4 = L_6,$$

is still completely true.

Further, when the two phases of the balancer are wound on one core and are interlaced, even though the out-of-balance currents which they respectively carry diverge in amount, yet L_7 remains $= L_8 = L$. It is only, therefore, necessary to make use of the final resultant instantaneous values for E_3, E_4, L_3, L_4 and L for insertion in our previous expressions, and they still remain true.

Thus the joint system of C_b and i is only affected by the superposition of the out of-balance components in virtue of alteration of the iron inductances.

The correct principle of superposition is, however, often wrongly stated. To superpose $C_0/2$ in different directions upon C_b in the external network is quite erroneous; to superpose $C_0/2$ in different directions upon the mean of the new final currents in the network, *i.e.*, upon $\frac{C_1 + C_2}{2}$, is, of course, right externally, but leads to an incorrect result in the armature.

Lastly, to treat the actual current in each limb of the balancer as composed of the alternating current i and a fixed proportion of the out-of-balance current $= C_0 n$, where n is the number of limbs or phases, is found to be only approximately correct.

(To be continued.)

CORRESPONDENCE.

THE NOMENCLATURE OF PRIMARY AND SECONDARY SOURCES OF LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The very interesting articles by Mr. Trotter and Mr. Harrison in your issues of May 19th and 26th make it perfectly clear that the science of photometry is in great need of clearly defined and universally recognised units. While one must strongly support Mr. Trotter's desire for a system of units which will appeal to the engineer rather than to the mathematical scientist, if we are to follow the excellent example set in the other branches of electrical engineering we must reach the practical engineering units through the scientific ones.

To my mind the confusion arises largely from the loose use of the regularly accepted term candle-power. This is a unit dating from the barbaric times when one gazed directly at a light source in order to estimate its illuminating power. Now, we turn our backs to the light and judge the illumination directly.

Candle-power, as Mr. Trotter states, is the English expression for luminous intensity, and I think most engineers regard it as a measure of the penetrating power of a point source of light in one direction. Thus, in a polar diagram, *candle-power is represented by a definite length or magnitude in a definite direction.*

Digitized by Google

This idea is based upon the law of *point* radiation—*i.e.*, the law of inverse squares.

Next, we have intrinsic brilliance defined as candle-power per unit area of light source. This quantity, apparently easily understood, seems to me an anomaly. If the light source has area it cannot (except by a conventional licence) be measured in candle-power; therefore, we may have candle-power or area, but we cannot have both together. In magnetism the unit pole is the basis of the system of measurements, or in electro-statics the unit charge. Both these systems bear a close analogy to the one under consideration, but, fortunately for the practical engineer, unit poles or unit charges do *not* exist; while, unfortunately, sources of light, which will obey the inverse square law experimentally, may readily be obtained.

The pole of a dynamo, for example, is referred to as producing a certain total magnetic flux and no attempt is made to compare it with the strength of a unit pole in one direction. A projector lamp, on the contrary, is usually absurdly rated as so many candle-power, the expression being absolutely meaningless. The correct method of stating the output of such a lamp would be in lumens, and would be found by measuring the mean illumination at any place along the beam of light and multiplying this by the area of the section of the beam. Mr. Trotter seems to object to illumination being defined as luminous flux per square centimetre; would he prefer to measure the density of a magnetic field in terms of feet and unit poles?

It therefore appears to me that, while candle-power is a very useful term for describing the luminous intensity in a definite direction of a light source of small dimensions, it should be reserved entirely for use in this relation. As at present employed, it sometimes means intensity and sometimes flux.

Mr. Harrison's remarks with regard to shadow-effect were of particular interest to me, as I have recently been working on somewhat similar lines. It seems, however, that there will be greater difficulty of definition than he imagines since there are "hard" and "soft" shadows, and while both help to define the outline of an object, and so, within limits, add to the effectiveness of the illumination, there is no doubt that the former is usually much more objectionable than the latter. The diversity of the illumination on opposite sides of a solid body would give no indication with regard to this most important point.—I am, &c.,

East London College, June 3. LEONARD MURPHY.

SOME NOTES ON THE USE OF TURBINE PUMPS IN COLLIERIES.*

BY R. H. WILLIS.

Turbine pumps for the unwatering of colliery and mine workings bid fair to oust the ram and other forms from colliery work altogether. Both the turbine pump and the electric motor are essentially high-speed machines, and therefore they can be direct-coupled. Running at comparatively high speed the combination takes up little space, and is easily handled, thus making it specially valuable for dip pumping, shaft sinking, &c. This type is, however, not confined to small quantities and low heads, but by adopting the multi-stage principle, it can tackle anything in the way of pumping water, however great the quantity or the height. For example, at the Powell Duffryn Steam Coal Co.'s Colliery, South Wales, there is a 900 H.P. electrically driven turbine pump in successful operation.

All turbine pumps have the following features:—One or more impellers, mounted on a shaft, revolving in suitable chambers, each delivering the water through a diffusion vane into the succeeding impellers, and finally into an annular space from which the water escapes into the delivery pipe. The chief improvement of recent years has been the provision of diffusion vanes. These take hold of the water after it leaves the impeller at a high velocity, and guide it into suitable passages until the velocity is comparatively reduced; the kinetic energy due to the velocity being thus converted into static energy. In the turbine pump there is no actual displacement of water as in a ram pump, as the action depends on the velocity imparted to the water, due to the revolving impeller, which velocity is ultimately changed into pressure head. Owing to this feature there is no necessity to provide relief valves on a turbine pump, as the pressure can never rise above that due to the velocity set up by the speed of the impellers. Consequently, the pumps can be started up with the delivery valve closed, and this is a great advantage as there is no chance of accidents happening.

The water always passes through turbine pumps in one direction, and is acted on equally by the impellers at all parts. Therefore, the water comes from the pump in a constant stream, and there is no need to provide air vessels as in a ram pump. This feature is a distinct advantage, as it prevents shocks to the pipe system and gives a steady uniform flow of water, allowing the use of the minimum size of delivery pipes.

One point in connection with turbine pumps of some designs, is the possibility of the motor being overloaded if working against a lower head than that for which the pump was designed. This is due to the fact that the surplus head expends its energy in increasing the velocity of flow of the water (consequently the quantity) in all parts of the piping and pump. The friction head is thereby increased and the efficiency decreased, and this artificial and inefficient load may exceed the normal power of the motor. It is general practice to make the motor some 10 per cent. larger than is normally required. Turbine pumps can be provided with special impellers, so designed that the variation of horse-power due to the variation in head is only a very small percentage. This is not altogether an advantage, as it often results in reduced efficiency.

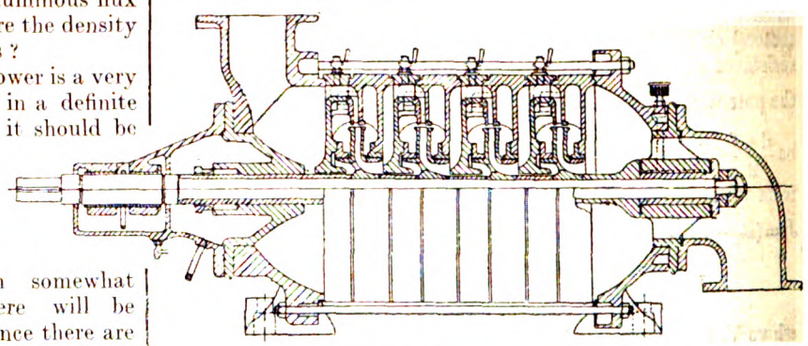

FIG. 1.—SECTION OF SELF-BALANCING TURBINE PUMP.

The greatest obstacle in the way of the satisfactory performance of turbine pumps has, in the past, been the difficulty of suitably overcoming the end thrust set up. In the earlier pumps, a ball thrust bearing or horse-shoe type thrust bearing was largely adopted, but these invariably gave trouble sooner or later. They were discarded in favour of what is known as the balance piston or plate. This device has held the field up to quite recently, but it is now in turn likely to be ousted. Instead of endeavouring, as was done in the older designs of pumps, to use the balance piston to balance the whole end thrust at once, the newer method is to destroy or neutralise the cause of end thrust where it is set up at each impeller. This is done by maintaining equilibrium on either side of each impeller by specially-designed passages connecting the chamber at each side of each impeller. This arrangement has been in satisfactory operation for some considerable time, and is, no doubt, the ultimate solution of the difficulty.

Another method of overcoming end thrust was to place the impellers back to back in pairs. Still another was to cause the water to flow in one direction through one-half the number of impellers and in the opposite direction through the other half. The thrusts set up in the halves of the pump are thus equal in value but opposite in direction, with the result that these two thrusts neutralise one another. Both these arrangements necessitate the use of an even number of impellers, which is not always convenient for the conditions under which the pump has to work. Their effectiveness also depends on equal leakage from all impellers to maintain the balance, and the castings are complicated and costly.

The author proceeds to describe and illustrate various types of turbine pumps. In his opinion there is no advantage in having an external casing, as it not only makes it more difficult to dismantle and re-erect the pump, but also adds very materially to the weight. For colliery work this additional weight is objectionable.

Fig. 1 herewith shows a self-balancing pump in which the end thrust is destroyed by equalising the pressure on each side of each impeller by means of the spiral passages connecting the chambers on the two sides of the impeller. This arrangement is very simple, and yet is very effective in operation. The reduction of the parts is a desirable feature, and simplifies and cheapens the design. A disad-

* Abstract of a Paper read before the West of Scotland branch of the Association of Mining Electrical Engineers.

Digitized by Google

vantage of the balance piston or plate is that as the wear increases in the neck rings of the impellers the leakage water tends to increase. The out-of-balance thus becomes greater, consequently more water has to flow from the interior of the balance piston, and as a result the efficiency of the pump falls off. If grit is present in the water this rapidly increases the wear of the rubbing parts and consequently the leakage.

Comparison of Ram and Turbine Pumps.—A great advantage that the ram pump has over the turbine pump is its ability to pump air and water. It can therefore be used in connection with unwatering a working, close to the face, where the supply of water is more or less intermittent. The turbine pump would be unsuitable under these conditions, as the presence of air in the suction side of a turbine pump is detrimental. It would constantly require to be re-primed.

If a very small amount of water has to be lifted against a very high head, then the turbine pump, while it is, of course, capable of doing the work, compares unfavourably with the ram pump. The number of chambers becomes excessive and the efficiency is low. With this exception, turbine pumps can be used for any work in connection with collieries.

Dip Pumping.—A condition which is very often met with in colliery practice is the unwatering of the "dook." Some engineers are of the opinion that this problem is unsuitable for turbine pumps. All difficulties can, however, be overcome, and the author's firm have several pumps installed for the purpose. The pump is mounted on a trolley which is so designed as to keep the pump horizontal. The pump starts against the minimum head, and as is the feature of all turbine pumps, it would, under these conditions, deliver more water

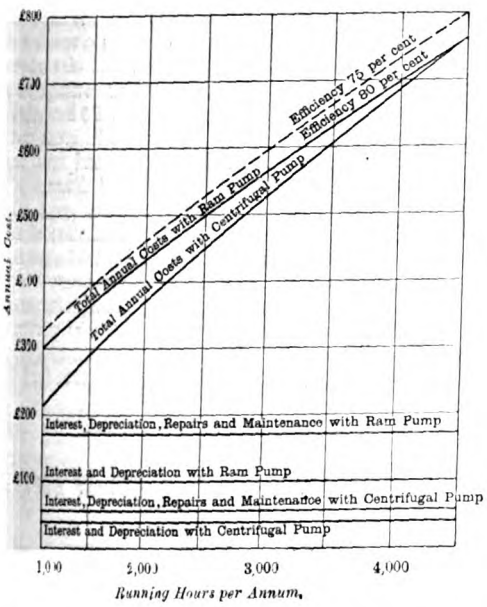

FIG. 2.—DIAGRAM SHOWING ANNUAL COSTS OF TURBINE PUMPS AND THREE-THROW RAM PUMPS FOR A FIXED OUTPUT OF 500 G.P.M. AGAINST A 600 FEET HEAD.

than the quantity for which it was designed. Consequently the motor would be overloaded unless some special steps were taken to prevent this happening. It is, of course, possible to throttle the discharge by means of a valve on the delivery pipe and produce an artificial head equal to the head for which the pump is designed, but this is obviously a wasteful arrangement.

The method followed by the author's firm (the British Electric Plant Co.) is as follows:—The pump is so designed that a varying number of impellers can be brought into operation, the chambers not required being replaced by dummy stages, which are removed as required. Only one impeller, say, in a four-stage pump need be in operation, all the remaining chambers in the pump being dummies, with, of course, a clear waterway through. The motor is some 10 per cent. larger than is actually required, and is of the variable-speed type. As the pump is lowered down, a shunt resistance is inserted in the motor field, and the motor speeded up until a point is reached when the head dealt with is equal to that of two impellers when running at the lowest speed of the motor. Two impellers are then put in the pump and the motor worked at its lowest speed. The same cycle of operations is followed until, ultimately, the pump has its full number of impellers. By this method the maximum of water is obtained with the minimum amount of current throughout the whole period, and the total result compares most favourably with ram pumps which have hitherto been always used for this purpose.

The same arrangement can be followed when the pump is driven with a three-phase motor, but it is not quite so flexible as with a direct-current motor. Consequently, use has to be made of a throttle valve on the delivery side, immediately after changing the impellers, so as to prevent the motor overloading itself at this point of the operations.

Sinking.—The turbine pump also lends itself very readily to the unwatering of vertical shafts. In this case the pump and motor are mounted with vertical-spindle motors and carried in a suitable cage, arranged so that the whole combination can be lowered down the shaft to follow the water as the level is reduced. In this case it is usual to prevent overloading of the motor by screwing down the valve on the delivery side so as to add an artificial head to the pump until it reaches a depth equal to that for which it is designed.

Relative Costs.—The following estimates for pumps to deliver 500 galls. per minute against 600 ft. head may be found of interest:

Specification of Turbine Pump.—Six-stage with 7 in. suction and 6 in. delivery branches. Internal parts of cast-iron and shaft of mild steel. Renewable cast-iron bushes at all internal rubbing surfaces. Direct-coupled by flexible coupling to three-phase squirrel-cage induction motor, 150 H.P., 50 cycles, 500 volts, speed 1,460 revs. per min. Both machines on one bedplate.

Specification of Ram Pump.—Horizontal three-throw, with cast-iron rams, 10 in. diameter by 15 in. stroke. Speed 41 revs. per min. with double reduction gearing, three-phase slip-ring type motor with interlocked short-circuiting and brush-raising device to give 120 H.P., 970 revs. per min., 50 cycles, 500 volts. Both machines on one bedplate.

With the above specifications as a basis, the following are the power calculations. It is assumed that the pumps run for 8 hours per day, and 365 days per year, so the total number of running hours per annum is 2,920:—

	Turbine.	Ram.
Output in gallons per minute	500	500
Head in feet	600	600
Water H.P.	91	91
Motor, B.H.P.	138	114
Input, electric H.P.	151	125
Kilowatts	113	93
No. of kw.-hours per annum	329,960	268,540

The life of the turbine pump may be taken as 10 years; that of the ram pump as 20 years.

Repairs and Maintenance.—7½ per cent. on the first cost of the turbine pump will allow for three complete sets of internal parts during the life of 10 years, also for renewing the cast-iron neck ring bushes every 18 months.

Efficiency (per cent.)

	Turbine.	Ram.
Pump	66	80
Motor	91	91
Combined	60·1	72·8

These efficiencies are lower than what may be obtained from new pumps as tested under favourable conditions, but they are considered fair average values for mining practice. When new, the makers would guarantee, probably, 70 per cent. and 85 per cent. respectively for the pumps alone.

	Turbine pump.	Horizontal treble-ram pump.
Net first cost of pump and motor, exclusive of control gear	£200	£750
Estimated cost of brick-built pump house with concrete foundations for pumps	40	115
Interest—5 per cent. on totals as above	12	43¼
Depreciation—		
Turbine, 10 per cent.	20	—
Ram, 5 per cent.	—	37½
Pump room, 2½ per cent.	5	18¾
Repairs and maintenance—		
Turbine, 7½ per cent.	15	—
Ram, 7½ per cent.	—	56¼
Pump room, 1¼ per cent.	2½	9½
Running costs for 2,920 hours at 0·33d. per kw.-hour, delivered at the terminals	458¼	373
Lubrication and packing glands	4	15
	£516¾	£553¼
Balance in favour of turbine pump	£36½	

If after running some time the efficiency of the ram pump comes down to 75 per cent., the balance in favour of the turbine pump on the above basis would be £67 per annum. The weight of the pump

Digitized by Google

and motor complete would be 3½ tons, and 18 tons for the turbine and ram pump respectively.

The cost in one case of preparing chambers, foundations, &c., for the two types of pumps was £240 and £900 respectively.

The number of hours during which pumping is carried on has considerable bearing on the question of relative costs between the two types of pumps. The curves given in Fig. 2 show the effect on the annual running cost of the turbine and a ram pump, according to the number of hours worked. The curves embody data relative to the 500-gallon pumps already considered, and the basis of comparison is the total annual cost inclusive of running and fixed or establishment charges. While the charge for interest is independent of the number of hours per annum during which the plant is in operation, this is not strictly true of depreciation, and still less accurate for repairs and maintenance. The error introduced by treating them as constant is nor great, and does not affect the value of the curves for comparative purposes. The vertical distance between the total cost and the total standing charge in each case represents the annual cost for power and supplies. It will at once be appreciated by a study of the diagram in what manner the comparatively expensive ram pump is handicapped. In fact, not until the pumps have run for at least 4,400 hours per annum (in this particular case) does the greater cost of power for the turbine pump outweigh its other advantages.

When considering the installation of a turbine pumping plant, the following features should be carefully considered :-(*a*) The pump should be capable of being easily dismantled and easily re-erected ; (*b*) all wearing parts should be made renewable, and all similar parts of similar pumps should be made interchangeable ; (*c*) effective methods should be adopted to obviate end thrust.

When the type of pump has been decided upon, the following points should be observed in fixing the same : (*a*) The pump should be fixed on solid foundations and set carefully in line ; (*b*) the suction pipe should be absolutely air-tight ; (*c*) an efficient foot-valve should be provided ; (*d*) the pump should be placed as close to the water to be lifted as possible.

DISCUSSION.

Mr. J. A. RUDD regretted that the author, instead of comparing points of similarity, had not dealt with the points of difference. Between the balance piston and the balance plate there was a very wide distinction. The omission of that distinction showed up weakness in Mr. Willis's design, which was practically the same as that now being abandoned on the Continent. The retention of thrust bearings also raised doubt in the author's mind as to the balance being effective. Then phosphor-bronze was admittedly better than cast-iron for impellers. Further, all makes of pumps were not equally efficient when new. He thought the author had made a slip surely in his figures in only allowing £50 for the pump. The Swiss undoubtedly showed the way for the method of dip sinking instanced by Mr. Willis. He criticised severely the difficulty of dismantling the type shown in case of repairs.

Mr. W. L. SPENCE thought Mr. Willis had treated the matter of end thrust—a very important point in turbine pumps—rather airily. Absolute balance was unattainable, to his mind, with varying loads such as in emptying a lodgment, and the increased vacuum developing on the suction side. So far as the sketches showed, the author had also no device for the balance being preserved on the outer casings. Such absence would inevitably, he thought, lead to destruction of the pump. Then he observed the author's pump alone had the motor at the pressure end. The tendency was to keep it away from the squirting water. To have a bearing as indicated inside the suction end casting seemed a bad engineering proposition.

Mr. S. A. SIMON remarked, as to the author's statement that 1,500 revs. per min. for alternating-current motors was the limit, that he knew of at least five motors in the district of 20 to 100 H.P. of the two-pole alternating-current 50-cycle type running at 2,950 revs. per min. satisfactorily for the past three or four years. He knew one firm had manufactured an aggregate capacity of 16,000 B.H.P. of two-pole motors varying from 100 to 1,000 H.P., running at 3,000 revs. per min.

Mr. WILLIS, in reply, said both Mr. Rudd and Mr. Spence had fallen into the same error. The small holes in the impeller—a feature of all makes of turbine pumps—had nothing whatever to do with the balance. Frankly he thought also the name balance-piston was a mis-nomer. In pumps of the turbine type forces were present to the extent of several tons in whichever style was used, either the piston or plate, and the potential danger attached thereto appealed to the engineer in a very disconcerting fashion. In the pump described these forces were balanced over the neck rings round the impellers, allowing the pressure on each side of the impellers to be equalised. This was how he arrived at a balance irrespective of load. As to the bearing at the suction end, there was no flow of water through the bearing as it was dead-ended, therefore no grit troubles could arise. Being surrounded by water little lubrication was necessary. As to ease of dismantling, he thought the spigot and socket arrangement simpler than the Swiss arrangement. The cast-iron was perfectly satisfactory, but he could give phosphor bronze if customers would pay for increased cost. He admitted Mr. Simon's point as to the two-pole alternating-current machines for 3,000 revs. per min.

WIRELESS TELEGRAPH INSTALLATIONS.

Messrs. Siemens Bros. & Co., Caxton House, Westminster, S.W., announce that, as they anticipate in the near future there will be an extensive field in wireless telegraph apparatus, they have acquired the British rights of the "Telefunken" system. This decision has, Messrs. Siemens state, been come to after mature consideration, as they have deemed it inadvisable to expend time and money in carrying out tedious experiments. The Company, however, have made a careful study of all the known systems of wireless telegraphy, and have come to the conclusion that the "Telefunken" system, introduced by the Gesellschaft für Drahtlose Telegraphie, of Berlin, offers the greatest advantages. They have, therefore, entered into arrangements by which they have secured the exclusive rights for the use of this system for the United Kingdom and for some of the British colonies.

The A.E.G. Electrical Co. of South Africa have acquired the rights of the system for the Union of South Africa.

Messrs. Siemens Bros. & Co. further inform us that they are now prepared to give estimates for the erection and equipment of wireless telegraph stations suitable for all purposes and also to contract for supplying complete telegraphic services under their own control on board ships.

At the same time Messrs. Siemens have issued a well-printed and profusely illustrated "pamphlet" of some 70 pages, which gives particulars of the origin and development of the "Telefunken" system. In Part I. a brief history of the system is given, and Part II. contains a sketch of its development up to a recent date. Excellent portraits of Profs. Slaby and Braun and of Graf Arco are included. Part III., which gives a fully-illustrated description of the new "Singing Quenched Spark" Telefunken system, contains a number of clear illustrations of instruments and apparatus, and also curves, &c., as well as particulars of the types of stations constructed on the new system, figures as to the efficiency of a 1·5 kw. station, &c. In Part IV. the chief advantages of the new Telefunken system are set out, and among these are small apparatus and small antennæ, large ranges, high speed, increased selection and decrease of atmospheric and other disturbances, tone resonance, great efficiency, noiselessness, large wave length, complete utilisation of the total energy in the receiver in consequence of singleness of wave, increased freedom from disturbance with loose receiver coupling owing to the slight damping, and complete utilisation of the high-frequency resonance owing to wave constancy. In Parts V. and VI. particulars are given of the stations erected, their locality, &c., and some interesting records of the new "Telefunken" system are set out in Part VII.

FIRST PUBLICITY CONFERENCE OF SUPPLY AUTHORITIES.

The Electricity Supply Publicity Committee held its first annual conference at the Institution of Electrical Engineers, Victoria Embankment, London, on Tuesday, May 30th. Mr. H. B. Renwick, chairman of the Committee, presided.

The CHAIRMAN briefly touched on the facts connected with the formation of the Committee, its aims and objects. He particularly emphasised the fact that this was the first time the officials of municipal undertakings and the officials of company undertakings had met together for the purpose of carrying on business in their mutual interest, and he hoped to see the principle of co-operation extended in other directions. The constitution of the committee was a particularly representative one. Its 17 members represented some of the most influential undertakings of the country, as would be noted from the following: Representing London municipal supply: St. Marylebone, Croydon, Hampstead, Hammersmith, Hackney, Hornsey, Beckenham, Representing the London companies: City of London Co., Charing Cross Co., Metropolitan Co., St. James' & Pall Mall Co., Kensington & Knightsbridge Co., Notting Hill Co., County of London Co. Representing the provincial undertakings: Brighton, Ipswich, Newcastle-on-Tyne.

The CHAIRMAN then ran through the leading features of the past work of the Committee. Successive issues of publicity literature had been made at frequent intervals throughout the year. These issues comprised posters, showcards, booklets, pamphlets, circulars, folders, leaflets, mail cards, postcards and adhesive labels, covering practically the whole of the field of electric supply. Further, the issues had been arranged so as to be appropriate to the various seasons of the year, and the shape and size of the publications had been carefully arranged so as to fall in with the general office arrangements of supply undertakings. The total sales during the year numbered nearly one million and a half. The entire result was perfectly satisfactory from every point of view, the Committee having supplied literature throughout the whole of the United Kingdom in addition to the colonies and abroad. The Committee had also done signal service in connection with newspapers, and the

Digitized by Google

various erroneous reports which had been given currency to in the Press in regard to the causes of fires. Corrections had been arranged in the Press wherever necessary, and the interests of electricity supply generally upheld. The chairman then invited suggestions from any of the members, chairmen or committeemen present.

Mr. W. A. Nicholes, of Great Grimsby, spoke strongly in support of a systematic advertising campaign, and of the considerable results which he had experienced in his own area. He also spoke very highly of the Committee's productions. He thought the time had now come when electric cooking should be energetically pushed.

Mr. H. R. Burnett, of Barrow-in-Furness, congratulated the Committee on the work they had done and the actual results which had been facilitated in so extraordinarily short a time, and said the whole of the industry was beginning to feel the benefit. He thought that the inclusion of an information bureau would be a good thing.

Mr. A. H. Shaw, of Ilford, suggested that the Committee should in the coming year issue large sized posters, as he thought there would be a great opening for same.

The Chairman, in reply, thanked the members for the various suggestions and criticisms, which, he said, should have the careful consideration of the Committee, and in reply to Mr. Shaw's suggestion said he hoped very soon to have some large sized posters to put at their service.

Mr. A. C. Cramb, of Croydon, on behalf of the municipalities, said how much they were indebted to the companies for the large share of the work which they had taken on their shoulders, particularly in this initial stage. He suggested that it would be very useful to have some arrangement for the registration of canvassers, to ensure being able to get hold of good men as representatives.

Col. Hopkins, of St. Marylebone, proposed a vote of thanks to the chairman, vice-chairman and hon. secretary, and spoke enthusiastically of the results which from his own experience had been obtained through the advertising propaganda. He thought there was a good deal to be said for Mr. Burnett's suggestion as to an information bureau. He suggested that competitive prizes should be offered for designs for posters, &c.

Dr. Mansfield Robinson, of Shoreditch, seconded, and spoke very appreciatively of the work done by the Committee. He thought it was the immediate duty of all the municipalities who had not yet joined the Committee to do so at once. He said that in the whole of his 20 years' municipal experience he had never seen in any department of municipal or public work such a record as that shown by this Committee.

The Chairman thanked Col. Hopkins and Dr. Mansfield Robinson for their vote of thanks, and the various members who had supported the Committee by their presence. He also mentioned the considerable assistance which had been given to the Committee by Mr. Cramb as vice-chairman and Mr. Walker as hon. secretary.

Mr. F. J. Walker (St. James' & Pall Mall Co.) spoke of the pleasure which his association with the Committee had given him, and hoped that the spirit of co-ordination between the municipalities and companies would be carried into the forthcoming Electrical Exhibition, as this would considerably help to impress the public.

ELECTRIC COOKING DEMONSTRATION AT HAMPSTEAD.

On Wednesday, Thursday and Friday last week special cooking demonstrations took place at the newly-opened showrooms of the Hampstead Corporation Electricity Department, 283, Finchley-road, N.W. These showrooms have been fitted up very attractively, and the attention of passers-by was drawn last week by laundry operations carried on in one window, electric irons being employed, and by a demonstration of the capabilities of a vacuum cleaner in another window.

The upstairs showroom has been fitted up for cooking demonstrations, and a lady attendant is to introduce in a practical manner electric cooking to the electricity supply consumers of Hampstead. The neighbourhood should certainly provide an excellent field for an extensive heating and cooking load.

The cooking demonstrations last week were given by Mr. F. Grogan, of the Berry Construction Co., and were undoubtedly the most interesting at which we have been present. Our only regret was that Mr. Grogan's audience was so small, for the convincing manner in which he substantiated the various claims made for electric cooking and for the "Tricity" apparatus in particular, could not fail to have won many converts. We understand that Mr. Grogan has during the last three months given a series of electric cooking demonstrations throughout the country with the most satisfactory results, the sales of "Tricity" apparatus during April being double those of March, whilst the turnover in May has more than quadrupled the total of the March sales. Such a result is convincing testimony that the public only require to have practical demonstrations of what electric cooking means and they will quickly see its advantages.

The "Tricity" cooker is already well known to our readers, as is also the extension cooker by which a top heat is provided for the oven; but we may draw attention to the fact that a two-gallon "Tricity" urn is obtainable and is usually fitted on the second hot plate of the duplex cooker. This provides a plentiful supply of hot water. Moreover, the two heats provided for each cooker enables two gallons of water to be raised to boiling point in about 70 minutes with an input of 800 watts, and to be maintained at that temperature by using only $\frac{1}{2}$ unit per hour. On the other hand, by filling up the urn the last thing at night and leaving the switch in the "low" position, the water will be ready at boiling point early next morning.

Other "Tricity" accessories to which attention may be called are a ham boiler, a fish kettle and an egg stand. This last mentioned fits inside the 3½ pint saucepan. By using only ¾ pint of water in this saucepan the eggs are steamed instead of boiled, and time and current are saved.

In connection with his demonstrations last week Mr. Grogan explained the importance of having flat bottoms to the utensils fitted over the "Tricity" hot plates if satisfactory results are to be obtained, and also the object of keeping the surfaces bright. This point was emphasised by means of a 4 lb. flat iron; although this was at the required temperature for ironing, no heat could be felt when the hand was placed at ¼ in. from the surface of the iron, provided it was bright. Moreover, the iron was still too hot to touch after standing for over one hour, due to the small radiation losses. The iron was heated in the first place in 4½ minutes by being placed on the hot plate. The ordinary black and rough surfaced flat irons besides being inefficient, owing to being excellent radiators, are also uncomfortable to use owing to the heat radiated on to the knuckles.

A striking demonstration of the capabilities of the "Tricity" oven was also given. A feature of this oven is that the heat is distributed evenly over the whole horizontal area, deflectors placed opposite the hot plates bringing about this result. As figures are of interest, we may mention that the oven was brought to a working temperature of 340 deg. in 20 minutes for an energy consumption of ¼ unit, which with current at 1d. per unit is equivalent to ½d. This result, the Company claim, cannot be obtained with any other form of oven.

A great feature of electric cooking, in addition to the improved flavour of the food, is the considerable saving in meat. This is emphasised by the following figures recorded in one test on a "Tricity" oven and for a coal range. The joint was a top side of beef:—

	Coal.	"Tricity."
Weight uncooked	5 lb. 4 oz.	4 lb. 0 oz.
,, cooked	3 lb. 6 oz.	3 lb. 8 oz.
Loss in cooking	35·7%	11·5%

This indicates that with electric cooking a 4 lb. joint is equivalent to a 5¼ lb. joint where an ordinary oven is used.

LEGAL INTELLIGENCE.

Johannesburg Municipal Council v. D. Stewart & Co. (1902) (Ltd.) and Others.

At Edinburgh on Tuesday Lord Ormidale commenced the hearing of this action, which was brought by pursuers against Messrs. D. Stewart & Co., Mr. Beardmore, and another for a declaration that they were entitled to reject certain gas producer plant, gas engines, two-phase alternators, direct-current dynamos, balancers and machinery and other goods contracted to be supplied by defenders, Messrs. D. Stewart & Co., to pursuers. Pursuers also claimed payment from Messrs. Stewart & Co. of certain sums, amounting to £418,694, as damages for breach of contract, and from the other defenders £115,134, being the principal sum contained in a bond dated April 13, 1907, granted by William Beardmore and the late Joseph Beardmore, as cautioners for D. Stewart & Co.

It appeared that in 1904 pursuers were desirous of introducing a system of electricity supply and tramways in the city of Johannesburg, and in May, 1905, entered into a contract with the defenders, Stewart & Co., to supply and erect the goods, plant, &c., necessary for the purpose, at a total cost of over £210,000. Messrs. W. and J. Beardmore were their sureties for the fulfilment of the contract. During 1905, 1906 and 1907 Messrs. Stewart & Co. delivered certain portions of the plant, and proceeded to erect them on the site at Johannesburg. The plant is alleged not to have been to specification. In 1906 Stewart & Co. were in financial difficulties, and in May of that year they intimated to pursuers that they were unable to perform the work, and abandoned it entirely on May 15, 1906. The portions of the plant erected on the site were of little or no value to pursuers, who in July, 1907, rejected the goods, plant and machinery, and claimed from Stewart & Co. repayment of the instalments of the price which they had paid (£143,095) and damages for breach of contract. Messrs. Stewart & Co. pleaded that the matter should be dealt with by arbitration, and also that in terms of the contract the matter should be decided by English law and in England. They denied breach of contract, and pleaded that the installation was according to the specification of pursuers, and that any failure of the installation to reach the prescribed tests was due to unsuitability of coal supplied by pursuers for gas-producing purposes.

Digitized by Google

A preliminary point of law led to an appeal to the House of Lords, who remitted the case to the Court of Session for proof on the grounds (1) that there being an averment that the whole contract had been repudiated by defenders, it was for the Court of Session to determine whether that was so, and whether, therefore, the arbitration clause could still be appealed to by them; and (2) that in any event, as English law would not compel an English Court to refer the matters falling under these clauses to arbitration, the Court of Session was not bound to refer such matters to arbitration, but had jurisdiction to entertain the whole case. In regard to the claim against the guarantors, the House of Lords reversed the judgment of the First Division, holding that as the bond bore that it was to be regarded as an English bond, it fell to be construed by English law, and that under that law the action was competently laid against the guarantors.

The first witness was the Town Clerk of Johannesburg, whose evidence occupied the whole of the opening day.

The case is expected to extend over three weeks, as numerous letters and other documents have to be produced.

PARLIAMENTARY INTELLIGENCE.

Telephones in Rural Areas.—The Assistant Postmaster-General (Capt. Norton) stated, in reply to questions in the House of Commons last week, that no distinction would be made in the provision of telephone party lines in rural districts or in the conditions of such provision between any part of the United Kingdom and any other part. Of course, those cheap party lines could only be provided in districts in the vicinity of existing telephone exchanges, or where there was enough telephone business to justify the establishment of new exchanges and their connection with the general telephone system of the country. No doubt this limitation would prevent to some extent the extension of telephones to farmers in England. The system could only be extended gradually. Those facilities could not be given throughout the country in places where the telephone did not, to some extent, exist at present. They could not cover the whole face of the United Kingdom with a network of telephones at tremendous cost.

New Acts of Parliament.—On June 2 the Royal Assent was given to the following Acts:—London United Tramways, Dover Corporation, London Electric Railways, Metropolitan District Railway.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Association of Teachers in Technical Institutions.—The conference of this association was held at Southport on Monday and Tuesday. The president (Mr. Barker North, of Bradford) in the chair. About 100 delegates were present, 12 branches being represented.

A series of resolutions relating to various aspects of technical education and the work of technical teachers were discussed.

The President, in the course of his address, said that the more one inquired into the various reasons given for England's failure to take the lead in industrial developments, the more one was driven to the conclusion that lack of the spirit of organisation and system, in both industrial and educational matters, was the root of the evil. The provision of an adequate number of preliminary trade schools and secondary schools with a technical bias was of the utmost importance. A characteristic feature of the present secondary system was that the education was too literary in character, with the result that youths were frequently pitchforked later into pursuits for which they were not adapted, or into professions which were overcrowded. Out of 157 holders of London County Council senior scholarships, only two were ultimately trained for industrial pursuits. They had to recognise clearly that provision must be made in the future for two distinct types of students—the first, the rank and file of the industrial army, and the second, the officers, who would have to organise and direct. Other questions were also of pressing importance—namely, (1) the necessity for the institution of a national "course" system, which should replace the present haphazard arrangement, and so that this might lead up systematically to the day work of the highest institutions; (2) the institution of a national system of examinations; (3) the necessity for placing the general organisation of evening schools on a more business-like footing.

Resolutions were passed in favour of an advisory council on technical education, the formation of consultative committees of teachers, the representation of teachers on education committees, advisory committees for juvenile employment, &c.

Mr. J. H. Reynolds, director of higher education for Manchester, said that as a nation we were spending £20,000,000 a year on elementary education, and it was a crime that a large proportion of that vast sum should go to waste. They had to lay hold of every boy and girl leaving school at 14 and carry on their education in some way or another to at least the age of 17.

Bangor.—On Wednesday the Council adopted a recommendation of the Lighting Committee to put in a Diesel oil engine and dynamo at the electricity works, instead of the present steam generating plant, at a cost of £2,000.

It was explained that the adoption of the recommendation would result in a total saving to the Corporation of £343 yearly. Application has been made to the L.G. Board for sanction to borrow £2,000 for the plant.

Darlington.—The salary of the engineer and manager of the electricity and light railways departments (Mr. Lunn) has been increased to £600 per annum, by three annual increments of £50.

Dudley.—The Council are recommended to apply for a loan of £5,500 for feeder and distributing cables and £1,080 for services, &c.

It is also proposed to increase the size of the condensing plant, fix a mechanical stoker to one of the boilers and replace an engine to enable the station to cope with the anticipated demand for the forthcoming winter. The cost of the work (£1,560) will be charged to revenue, and payment be extended over a number of years.

Imperial Conference.—At the sitting of the Imperial Conference on Friday various questions of importance to commercial men were discussed.

Arbitration Awards.—The following resolution, by Mr. S. Buxton, M.P., was referred to a committee: "That the Imperial Government should consider, in concert with the Dominion Governments, whether and to what extent and under what conditions it is practicable and desirable to make mutual arrangements with a view to the enforcement in one part of the Empire of commercial arbitration awards given in another part."

Uniformity of Patent Laws.—A resolution by Sir Joseph Ward, "That it is in the best interest of the Empire that there should be more uniformity throughout its centres and Dependencies in the law of Copyrights, Patents, Trade Marks and Companies" was agreed to.

Weights and Measures.—A resolution in favour of the decimal system was withdrawn.

International Exhibitions.—Mr. S. Buxton moved "That in view of the International Conference to be held at Berlin in 1912, with a view to the regulation of the conditions under which International Exhibitions should receive support, it is desirable that the Imperial and Dominion Governments shall consider the matter in conjunction so as to arrange if possible for concerted action on this subject." After discussion, this was agreed to.

Inland Telegraph Charges.—In matters relating to land telegraphy Belgium has always been in a foremost position. The development of land line telegraphy has, ever since the days of Van Rysselberghe, been a subject for which the world has much to thank the Belgium telegraphic department. "The Times" correspondent at Brussels, under date May 24, refers to negotiations regarding reductions in telegraph rates, subject to special conditions, between Belgium, on the one hand, and Great Britain, France and Germany on the other. The Belgium authorities have inaugurated a system of telegraphic subscriptions. Newspapers, business houses and other large users of the telegraph day by day, by payment of a subscription representing about one-half the ordinary rates, are enabled to transmit their telegraphic messages. The only condition attaching to this arrangement, which Belgium is the first country to adopt, is that there shall be a minimum of 250 words per day to be paid for, and that the messages shall be transmitted between stated hours. Belgium is endeavouring to obtain the consent of Great Britain, France and Germany in order that the arrangement may be applied to telegraphic traffic between these countries.

Inquests.—Adjourned inquiries were held last week into the deaths of two men who were recently killed at the Sherburn Hill colliery and the Lumley Third Pit of the Lambton Collieries Co.

At Sherburn Hill the inquiry related to a hand putter named Laverick, who met his death on April 28. Mr. Robt. Nelson, H.M. electrical inspector of mines, and Mr. A. D. Nicholson, chief inspector of mines, were present.

WM. WALKER, coal filler, said that on April 28, after Laverick had brought out his full tub and taken the empty one in he sat down on the rails. Witness was standing beside the empty tub (3½ yds. away), and whilst talking to Laverick and to a man named Ashworth, the latter shouted out to Laverick, "Keep back, the tub's off the way." Just as he shouted, and when Ashworth was getting round the turn, the place where Laverick stood lit up. A man named Nutter switched off the current. Several men applied artificial respiration upon both Ashworth and Laverick. They succeeded in reviving Ashworth, but not Laverick. When Ashworth's tub was off the way it was quite clear of the cable, but where deceased sat he thought he caught his head against the cable. He had not heard of anything like that happening before, but he had had many a shock before when he was pulling tubs through catching the cable in a bare place. He had not reported those matters because he never thought anything of them until this accident occurred.

By Mr. NICHOLSON: He had never observed that in the haulage roads the cables caught the tubs. He could see the blue light on the plates when the place lighted up. It was five minutes after the accident before current was switched off.

In answer to the foreman (Mr. Errington) witness said he had had a few shocks, and others had more shocks, but he did not frequently come across places where the cable was worn. He had never seen the timber set on fire by any flashes.

GEORGE TURNBULL, driver of the coal cutter, said that on the morning in question Walker shouted that someone was caught in the face. He stopped the coal-cutting machine at once and went along the face to see what had occurred. He saw deceased lying face downwards, his face touching the side of the rail. He used artificial respiration to try to bring him round, and was so engaged close upon half-an-hour, but without result. Prior to that he had given orders for the current to be cut off at the out-bye switch box. There was no flash when he was there, and he did not see any defect. He could not give any explanation of the accident. He had had some trifling shocks from the cutter, but not from the main cable.

Mr. NELSON said cases had been known of life having been restored after two hours' treatment. He did not want to cast any reflection on Turnbull, but the more widely this was known the better, because efforts ought not to be stopped so soon.

Mr. BELL (for the Colliery Co.) said that the cables had been greatly improved of late years.

Mr. NELSON: I understand you to say that you repair worn cables with black tape. Are you satisfied that you can make a good job of it?—Turnbull: Yes.

Do you consider it a satisfactory job to cover up a bare part with black tape alone?—It is quite safe for a time, just with black tape.

For the time being?—Yes; and I report the matter to the electrician.

By Mr. HEATH (for the Miners' Association): The rails were still electrified, but Laverick was not touching the cable then. There must have been some connection between the cable and the rail.

PATTERSON, a foreman electrician, said he examined the electric apparatus at 10:30 a.m. on April 28, shortly before the accident. He

Digitized by Google

examined the cables and switch boxes in the second east district and found all was safe and in order. The cables were properly insulated. When he heard of the accident he went straight to the scene and saw Turnbull, who told him what had taken place, and showed him the exact spot. On the way he met deceased and Laverick being taken out-bye. He examined the cables, and found one damaged. The insulation had split about ¾ in. He found the copper was not bare, and he had to probe with his screwdriver to find it. The cable had been jambed, probably by a tub, and that caused it to split. The tub that jambed it would act as a conductor, and form a connection. That was what he should say was the cause of the accident. He thought it would be the empty tub that Ashworth was putting that caused it. Ashworth would not get so severe a shock, as he would be standing on the ground, whilst Laverick was actually sitting on the rails.

In reply to Mr. NELSON, witness said the cable seemed to be in the same position after the accident as it was before. His private theory was that the empty tub coming in-bye got off the way, and in putting it on again it must have jumped and struck the cable. He knew there was a rule about cables and tubs, but in that case the cable was closer to the tub than it should be, because they were going to shoot the canch down.

By Mr. HEATH: He did not agree that the electrical system adopted at the colliery was dangerous, although personally he preferred the alternating system. He thought armoured cables were safer than rubber cables.

Other evidence having been given, the Coroner summed up. He did not think the matter had been definitely cleared up. There was no evidence to show that the empty tub was off the way. There was no evidence of negligence on the part of the management. The report of the local inspectors was to the effect that they, as practical working men, had examined the place and found the cables in good order.

The Foreman expressed surprise that the defect in the cable was not discovered.

The jury then returned a verdict that Laverick's death was caused by injuries accidentally sustained from an electric shock through coming in contact with an electrified rail whilst following his employment.

In the second inquiry, the deceased was John McPherson, who had been an electric conveyor operator at Lumley Third Pit.

After medical evidence had been given to the effect that death was due to paralysis of the brain due to electric shock,

Mr. NELSON asked Dr. J. R. Hall, a medical witness: Is this the first post-mortem you have held in a case of this kind?—Yes.

And you are not able to say from the condition of deceased whether it was a case of death from high or low pressure?—No.

But the indications were so marked as to show that the man died from electric shock?—Yes, in my opinion.

GEO. COULSON, deputy overman, said McPherson seemed to understand his work. He last saw McPherson alive at 10 a.m. on May 13. He was then at the motor, but no conversation passed. Witness went to the other end of the conveyor, and subsequently returned to the motor end. When he got to the switch box he heard the motor humming, which meant there was something wrong with it. He at once switched off the current, and going to the motor found McPherson lying on his left breast, with his nose and mouth to the ground. There was some water between the sleepers and the rails, and his face was in it. He tried artificial respiration and continued it for an hour and a half, and meanwhile the doctor came. Witness was first to McPherson, but he seemed lifeless when he picked him up. That morning witness and deceased had got slight shocks off the motor, and he reported the matter to the foreoverman, who had the machine stopped, and the electrician was sent for. In the morning he received a shock through touching the motor with his elbow when he was on a canch. He had heard another man say he had had a slight shock from the fan. He did not know whether McPherson had any shock. There was no necessity for deceased to touch the motor.

LAWSON, an apprentice electrician, said that on May 13 he got a message that the electrician was wanted down the pit. He could not find the chief electrician, so he went himself. He met deceased, who told him the motor was a bit "tickley." Current was shut off, and witness went to the three leads from the cable into the motor. He took the top one off first, and found the small strands had been catching the side of the framework of the motor, and had been burnt away. He tightened the strands up and put some rubber tape and black tape around them. The other two leads were found to be all right. He then switched on the current, and found everything was right. He got no shock, although he stayed there a quarter of an hour.

By Mr. NELSON: The machine frame had never been alive before when it was running. He had several times made those connections, and thought that what he did was an effective way of making the connections.

By Mr. HEATH: The leads were fixed to the cables. The risk would be obviated if the leads fitted into the holes of the motor, and without having to pare off the strands.

Mr. R. DOBBING, chief electrician, said that Lawson reported to him the result of his examination of the motor and leads. He considered that what he had done was quite right and proper. When witness went down the pit artificial respiration was being applied to deceased. He examined the motor the previous night, and found everything all right.

By Mr. NELSON: There was a previous case reported of a shock from a cutter, but that was the first time he had had a report of a shock from a motor frame. That would indicate a fault in the machine, and also that the earth connection was imperfect.

By Mr. HEATH: He had been at the colliery three years, and with the exception of one shock from a coal-cutter had never heard of another shock.

Mr. H. J. FISHER, engineer to the Lambton Collieries Co., said he examined the motor and machinery about three weeks previous to the accident. He had not heard of any shocks previous to the accident. He made an examination of the machinery after the accident to see if it was properly earthed, and he also examined the continuity of the earth to bank. Tests were taken and they were entirely satisfactory. That proved that it was impossible to get a shock from the framework of the motor. He knew of the repairs done to the motor, and thought that confirmed the impossibility of getting a shock. He thought there must have been an intermittent break in the earth. The humming of the machine was intermittent, and that was proved by it not humming one day, but doing so on another day after the accident. The earth plates at bank had been tested, and found satisfactory. The earthing of a portable machine like the motor was not compulsory.

By Mr. NELSON: The boy might have inserted his fingers in the terminal box, and thus have got a shock. The motor was humming when he made the test. He did not regard the terminal box as an ideal method of connection with the motor, but it had been in operation there and elsewhere for several years without an accident. He did not think it necessary to alter it, but they were doing away with the terminal box and putting in a plug box and automatic switch.

By Mr. HEATH: There was a great deal of vibration with the motor, which might easily slacken the nut in the motor frame, and thus weaken the connection. The boy would only have to slide the terminal cover to one side in order to put his fingers in.

Other evidence having been given, the jury came to the conclusion that McPherson was killed by an electric shock accidentally received, and recommended that experienced men only be employed to attend to electrical machinery.

L.B. and S. Coast Electric Train Service.—The improved service of trains on the London, Brighton and South Coast Railway came into full operation on the 1st inst. by the opening of the complete electric service between Victoria and the Crystal Palace.

By the electric train service displacing the steam trains on certain journeys there are 97 down trains daily instead of 72, and 113 up trains instead of 82, running from Victoria to Wandsworth Common. There are also a number of through business trains from London Bridge to Wandsworth Common morning and evening. During the day the only change necessary for residents in that district is at the Crystal Palace, and in a few months' time through electric trains will be running between London Bridge and Wandsworth Common, as the electrification of this road is nearing completion.

London Electricity Supply.—A return prepared by the assistant statistical officer of London County Council (Mr. J. J. C. Spensley) has been issued, giving particulars of the electricity undertakings in and around London.

The return shows the various authorities under the Electric Lighting Acts, with their areas of supply, and an analysis of the accounts of each undertaking for the year ended March 31, 1910, or December 31, 1909, and also various miscellaneous statistics relating to capacity, output, average prices obtained for current, assessments, &c. The publication, although somewhat belated, is interesting, inasmuch as it contains a number of tables, which enable a ready comparison of the figures of one undertaking with another. In addition to the undertakings in the metropolitan boroughs, statistics are given of those in Greater London and a few places on the outskirts of the metropolis, such as Grays, Gravesend, Chislehurst, Watford and Weybridge. Figures relating to the North Metropolitan Electric Power Supply and the South Metropolitan Electric Tramways & Lighting Co. and undertakings taking electricity in bulk are also included.

Miners' Safety Lamps.—In his monthly circular to the Northumberland Miners' Association Mr. Thos. Burt, M.P., makes reference to the prize of £1,000 recently offered by a colliery proprietor (through the Home Secretary) for the best electric safety lamp fulfilling certain specified requirements. Particulars of the prize were given in the ELECTRICIAN for June 22 (p. 283).

Mr. Burt points out that some years ago it was thought that electrical engineers would supply a greatly improved safety lamp. Many portable lamps were invented and exhibited from time to time. Some of the initial difficulties, such as the too great size and weight of the lamp, were overcome. One of the drawbacks, however, which remained unsolved was that the electric lamp could not be used for testing the presence of gas. That difficulty, he was told, was likely to be surmounted. Owing to the very imperfect light afforded by many of the ordinary safety lamps, the miner was always under a temptation to work with a naked light. It should be borne in mind, too, that insufficiency of light was often itself a source of danger. Hence a genuine safety lamp, giving a good, serviceable light, would be a great boon to the miner, and would be likely to largely diminish the number of accidents.

In reference to this matter, the Dalkeith miners, on Saturday, passed a resolution calling for the deletion of the sub-section of the Mines Bill making the use of safety lamps compulsory. It was considered that the imperfect illumination by safety lamps would increase accidents when open lights could reasonably be used.

Provisional Order Revocation.—The Board of Trade have revoked the Stevenage Electric Lighting Order, 1902, as from May 30.

St. Pancras (London).—Last week the Council approved the recommendation to reduce the charge for current for outside shop lighting to 3d. per unit.

Digitized by Google

South Shields.—The L.G. Board have now sanctioned the borrowing of £7,580 for providing additional plant at the electricity works.

Three inquiries were held by the L.G. Board with regard to the Corporation's application for permission to borrow money, and in February the Corporation revised their schemes, and the Board's inspector held the inquiry last month, when the application was opposed by the N.E. Railway Co. and Smith's Dock Co. The estimated cost of the new plant is £8,000, of which amount it is proposed to borrow £7,580, the balance £420 being taken from reserve fund.

Spennymoor (Durham).—The Council have invited the local electricity supply and gas companies to tender for the public lighting of the district for 12 months.

Stoke-on-Trent.—An inquiry will be held on Wednesday next into the application of the Council for sanction to borrow £60,000 for the erection and equipment of a new generating station.

Submarine Cable Rates.—Following on the very specific statement made by the Postmaster-General in Parliament and by the Chairman of the Eastern and Associated Telegraph Companies to the shareholders of these undertakings, "The Times" correspondent in Paris, under date June 4, informs us that "a reduction of 50 per cent. is recommended to be made in the charges for long-distance telegrams transmitted by submarine cables in clear language." This is, we think, exactly the rate mentioned by the P.M.G. and Sir John Wolfe-Barry.

Tramcar Accident.—On Monday morning an accident occurred on the tramways of the Stalybridge, Hyde, Mossley and Dukinfield Tramways and Electricity Board, and several persons were injured. At a sharp curve at the foot of an incline the car left the rails and was overturned.

Lieut.-Col. von Donop opened a Board of Trade inquiry into the accident on Wednesday.

John Sapper, driver of the car, in reply to the Inspector, said he had charge of the car before that accident. On previous runs he had had no trouble in running down Millbrook. He brought the car to a stop at the top of the Millbrook-hill, and in doing so used the hand-brake. He did not use the magnetic brake in making the stop.

Inspector: That is different from what you told me last night?—Yes.

You told me distinctly that you stopped the car by means of the West-inghouse brake, that is, the magnetic brake, and then applied the hand-brake?—No. I said I used nothing but the hand-brake.

Witness added that he waited at the top until he got the signal from the conductor. Describing the journey down hill, he said: "I had released the hand-brake, and simultaneously applied power to the third notch. The car moved forward, and gradually gained speed. When I had sufficient speed to generate current to bring the magnetic brake into action, I applied some sand and applied the magnetic brake by degrees, on account of the rails being very moist. I noticed that when the brake was on the second notch the car was gaining speed quicker than I expected. I then commenced to drop sand, but the car did not retard at all. I gave the magnetic brake another two notches, but I could not make the first curve, including round the first curve. I could not pull up at the second curve, which I made stopping place, and I put that down to the wheels skidding. Then, when I got out straight again, I put on the magnetic brake to the highest point was reached, but as the car kept going, and gaining speed, I came to the conclusion that the magnetic brake had failed. So I shut it off, and applied the hand brake to go round the curve at the bottom. Though the speed was high I thought as we kept the rails we would get over the curve, but the passengers on the top were excited and did not keep their seats. Instead, they got on the right-hand side. The car left at the curve and the heavy side weight turned it over on its side."

Inspector: When you started downhill did you think the wheels were skidding or did you know where they began to skid?—Witness: I did not know, but when I put on the magnetic brake the car gained speed. I thought the wheels were skidding owing to the bad state of the rails. I am sure the magnetic brake did not act going down the hill."

Did you try the magnetic brake at the last stop before starting down hill?—No, sir.

Albert Shaw, the conductor, said the car carried 42 passengers on the journey, and the usual stop was made at the top of Millbrook-hill. Several passengers, who travelled by the car, denied that the car was brought to a standstill at the top of Millbrook-hill.

The inquiry was adjourned.

Underground Telegraph Cables.—In a recent report by the Postmaster-General it was stated that the main underground telegraph scheme in the west had been completed, and the wires between London and the landing places of the important cables starting from the west coast had been diverted to the underground route.

It was stated that an underground line had been completed to Edinburgh; a length of underground work from Aylesbury to Coventry had been laid down, completing the second London-Birmingham underground cable, and cables had been laid down between Manchester and Stockport, Manchester and Ashton, and Manchester and Stockport; cables had been laid between Leeds and Stockton, Chatham and Canterbury, and Berkeley and the city boundary of Gloucester. During the year it was hoped to lay pipes from Gloucester to Worcester, from Beverley to Hull, and from Canterbury to St. Margaret's Bay and Abbot's Cliff, the landing places of Continental cables, and cables from Berkeley to Worcester. The cable from Stockton to Leeds was practically finished, and would complete the line from Warrington to Newcastle. The pipe work from Gloucester to Worcester and the cable from Berkeley to Worcester would complete the underground connection between Bristol and Birmingham. There would then be a triangle of underground lines with the angles at London, Birmingham and Bristol, the underground lines to the south-east, the north and the south-west being extensions from these three towns.

Wanstead.—On the invitation of the Council, West Ham Corporation are considering the question of constructing a tramway along the centre road across Wanstead Flats.

It is suggested that West Ham should promote a bill for a double line across the Flats and round Bushwood to Leytonstone, with inter-running powers over the new section with the East Ham, Leyton and Walthamstow Councils.

Wrexham.—An enquiry was held here on Friday into the application of the Council for sanction to borrow £4,145 for the electricity undertaking.

The town clerk (Mr. Lawson Taylor) gave particulars of outstanding loans, &c. There was, he said, an overdraft of £728 on the electricity account, but while debit balances in connection with the undertaking had affected the rates to the extent of £3,353, £290 had been credited out of subsequent profits, the latter totalling £1,134 in addition, which at present was placed to reserve. The total loans sanctioned for electricity works amounted to £41,856, of which £10,459 had been paid off. Last year the profit was £503 (against £343 in the previous year).

The Inspector (Mr. T. C. Ekin) observed that the undertaking owed £3,050 to the rates. They started off very well by putting their first profit of £270 to relief of rates, but after that they stopped. Why?

The Town Clerk replied that receipts from the rates were not regarded as a debt. The reserve fund was started in compliance with a strong representation from the L.G. inspector who held an enquiry into a like application three years ago.

The borough accountant (Mr. Rogers) and the borough electrical engineer (Mr. W. G. Pickvance) also gave evidence. Mr. Pickvance stated that there had been a progressive increase in the consumption of electrical current from 306,268 units in 1903-4 to 646,883 in 1910-11.

Mr. Hugh Jones (for the local gas and water companies) tried to ascertain the proportion of the profits from wiring to the aggregate profits, which, he alleged, constituted an illegal source of income; but the Inspector said the question had nothing to do with the enquiry.

By agreement, £130. 6s. 4d. was eliminated from the total applied for.

COLONIAL AND FOREIGN NOTES.

Argentina.—The "Review of the River Plate" says the Electric Light Council of Montevideo have finished their study of the project for acquiring all existing electric light stations by the Government and the erection of further stations in important towns. The administration of all the stations will be under the control of the Council of the Electric Light Stations of the Uruguayan Republic.

Mr. McClelland, consulting engineer for the electrification of the Central Argentine Railway line to the Tigre, left Argentina for England on April 21 to order the necessary material.

Campana Council have been authorised to place a contract for the electric lighting of the town.

San Fernando Municipality have cancelled the concession granted to the Compania Argentina de Electricidad for public lighting, and will shortly call for tenders for the erection and equipment of a generating station.

The Cia Franco-Argentina de Electricidad, who recently obtained a controlling interest in the Anglo-Argentine Electric Light Co., have decided to increase their capital to $10,000,000.

Canada.—The Alberta Electric Railway Co., which was formed last October with a capital of $10,000,000, will commence work on the construction of an electric railway from Medicine Hat to Banff, via Calgary, with branch lines extending to Taber and Macleod.

The construction work of the electric railway from Guelph to Berlin has been completed, and the line will ultimately extend from Toronto to Detroit (U.S.A.). The company will take its motive energy from the Government's Hydro-Electric Power Commission.

Canary Islands.—An electric tramway between Las Palmas and Puerto de la Luz (four miles in length) was completed last August, and an excellent service of cars has since been running.

Engines, boilers, iron chimney, cranes, machinery and tools which have been imported in connection with this undertaking are all British, the pumps are American, rails and iron work for buildings are Belgian, batteries Spanish, cables French, and dynamos, switchboards posts and cars German.

France.—The electric lighting of the port of Pallice, for which current is at present supplied direct from the Rochelle station, is to come into the hands of the Chamber of Commerce, which will have a transforming station at the dock to supply the quays and warehouses.

India.—"Indian Engineering" states that arrangements were recently made for fitting 45 ceiling fans and 107 pendant electric lamps in the four blocks of buildings occupied by the engineering and

Digitized by Google

traffic employés of the East Indian Railway at Howrah station. The remainder of the staff quarters had already been provided with electric light and electric fans.

On the Burma railways a trial is to be made with Stone's electric train lighting system. Some carriages on the line are fitted with the Vicarino-Crawford electric lighting system, but nearly all trains are lighted with oil.

A tender has been received for the electric lighting of the public offices of Lahore, and a contract will probably result. The contracting company will also have the right to supply private consumers.

A new power house has been built for the North-Western Railway at Lahore, and authority has been given for the purchase of plant. The plant in the old power house (and which will be removed to the new power house) includes two 125 kw. and one 250 kw. sets with two Stirling boilers and a Babcock boiler. The station as completed will contain four 400 kw. Browett-Westinghouse, and two 250 kw. and two 125 kw. Howden-Lancashire steam turbine sets; five Babcock and five Stirling boilers, with Babcock & Wilcox chain grate stokers. Weir three feed pumps, one Hayward-Tyler three-throw electrically-driven pump (Lancashire dynamo motor), one centrifugal Worthington pump (Lancashire Dynamo motor); one Leblanc type central low level jet condensing plant for 41,000 lb. steam per hour with rotary air and water pumps; enclosed assisted draft type cooling tower and main switchboard (by Whipp & Bourne). The transmission is overhead, and the internal wiring is carried out with v.i.r. cable on porcelain cleats except where leads have to be taken along floors or in other places where mechanical protection is necessary. In such cases heavy gauge screwed conduit with insulated lining is employed.

At the workshops are also a number of electrically-operated overhead travelling cranes and traversers, the equipment for which was supplied by the British Thomson-Houston Co., the Lancashire Dynamo & Motor Co., and the British Westinghouse Co.

Italy.—Concessions for the construction of electric tramways have recently been granted to the Soc. Anon. Tranvi di Mestre for lines from Mestre to Carpenedo and Mestre to Treviso and Sant' Artemio, with branch from Piazza dei Noli to Port Cavour station; to the Soc. Varinese par Imprese Elettriche for extensions to Monte Tre Croci, and to Santa Maria del Monte; and to other concessionaires for a line from Como to Erba Incino.

A consular report on the Genoa district for 1910 states that the new electric railway from Genoa to Busalla, on the way to Turin and Milan, is now working.

A new direct bronze telephone wire is working very satisfactorily between Genoa and Rome.

In Genoa there are 94 miles of tramways, with 304 electric cars and 147 trailers in use; 7,951,592 car-miles were run in 1910, and 61,152,935 passengers carried. Receipts were £333,636, and gross profit was £146,873. The employés number 1,518.

The two electric tramway companies in Turin have constructed two new lines to Borgata, Lingatto and Pozza Strada, both extending about two miles from Turin.

The Società Elettrica Riviera di Ponente Ing. Negri, which was formed to utilise the water power of the Roia, has found it necessary to build at Savona a steam-driven generating station as a reserve for emergencies. The company supplies power to the Soc. Siderurgica of Savona, to the local gas company and to several small towns and villages, including Albisola and Celle.

Japanese Submarine Cable.—A consular report on the trade of Nagasaki for 1910 states that the total imports at Nagasaki showed a decrease of £40,198 compared with 1909, although there was an increase of about £85,000 in submarine cable, the cable being for the new telegraph line from Mogi to Tamsui (Formosa), 655 miles in length, which was supplied from the United Kingdom, and was put into service in October, 1910. The total imports of submarine cable (all from the U.K.) were valued at £102,254.

Russia.—The municipal authorities of Ekaterinoslav propose to raise a loan of 2,600,000 roubles (about £274,000), of which about £105,000 is to be spent on tramway and other works. The Council of Ministers has agreed not to oppose the proposal.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Brighton.—The accounts of the electricity works for the year ended March 31 were presented to and approved by the Council last week.

The total amount borrowed is £816,848, an increase of £24,000 during the year. The total income was £98,821, including £60,188 from lighting supplies, £6,568 from power, £4,558 from special contract supplies, £407 from bulk supply, £10,116 from tramway supply and £12,044 from public lighting, sundry revenue being £4,940. The total expenses (£49,555) included £28,683 for generation, £4,291 distribution, £4,500 public lamp maintenance, £4,084 rent, rates and taxes, £6,606 for management and £1,225 special charges. The gross profit was £49,266, and after paying interest (£18,931) and sinking fund (£25,584) there was a net profit of £4,752, against £6,252. The total works costs were 0·73d. per unit sold (against 0·7d.) and the total costs, including loan charges, 2·05d. (against 2·19d.). The weight of coal consumed per unit sold was 5·26 lb. (against 5·95 lb.), and the average cost was 13s. 3¾d. (against 12s. 4¾d.). 10,285,680 units were sold (4,193,701 lighting, 1,478,200 power, 2,023,109 tramways and 1,034,681 public lamps), against 9,041,844; there are 5,239 consumers, against 5,020, and the number of 8 c.p. lamps connected was 375,099, against 363,124. The maximum load was 5,140 kw., against 4,727 kw., and the load factor was 22·8 per cent., against 21·8 per cent. There are 2,220 public electric lamps (arc and incandescent), an increase of 20.

In an interesting report the engineer and manager (Mr. John Christie) gives particulars of the plant and mains extensions during the year. The total amount provided for redemption of debt by sinking fund is £265,558, or 33 per cent. of the capital. They sold 1,243,836 more units (13½ per cent.) than in the previous year, and owing to the better load factor and various economies in the operation of the steam generating plant, they had been able to reduce substantially the weight of the coal consumed per unit sold, and thus, in spite of the considerable increase in the price per ton, they had been able to generate the additional output for an extra expenditure of only £1,195, thus neutralising the increased price, and the cost under this heading per unit generated had fallen from 0·40d. to 0·38d. Repairs and maintenance showed a considerable increase of £3,510 (equivalent to 0·06d. per unit), due to the alterations to the high-tension switchgear, oil cooling, hot well and circulating water pipe systems, and repairs to sea defences. These would not be recurring charges, and when completed would have brought their plant thoroughly up to date. There was an increase in the units sold under every head. For private lighting the increase was 100,880 units and he (Mr. Christie) considered they could now fairly assume that they had passed the low water mark in their progress brought about through the general use of the metallic filament lamp, and with the additional business, which they might reasonably count on obtaining, their sales under that heading should in future years show steady annual increments. The output for power showed the substantial increase of 336,800 units. During the year 21 additional motors (94 H.P.) had been hired to consumers. The number now let out is 210, representing a total of 1,041 H.P., and the demand from these, together with the extra electrobuses which the company had added to their fleet was responsible for the increase. With the great improvements which were being effected in heating and cooking apparatus, however, a fresh field was opened up for development, and it would shortly be necessary to consider what steps they should take to meet the probable requirements of the consumers in that direction. The sales to public lamps showed a small increase of 19,575 units, due to a few additional lamps having been erected, and to the 60-watt standard metallic filament lamps being now universally used throughout the whole area for side street lighting. The average candle-power per post during the past few years had been increased by at least 50 per cent., while the total cost to the town for street lighting furnished by their department showed a saving of £80 over last year. The output to the trams had increased by 84,804 units, and the reduction in the price of current from 1·35d. to 1·2d. per unit had further benefited that department to the extent of £1,264. The bulk supply to Aldrington showed the satisfactory increase of 12,046 units, and they had now 152 consumers with an equivalent of 6,247 8 c.p. lamps connected. The Aldrington revenue was £407, or 24 per cent. increase. The railway company had also put down more electrically-driven plant, and the quantity sold to them under special contract now approached the estimated maximum for which provision was made. The power supply to Messrs. Smith & Son's mill, Portslade, was started up in February last, and the results so far had proved most satisfactory. The substantial increase in output had not proportionately increased the maximum demand on their generating plant, the load factor having increased 22·8 per cent., as the result of more economical operation. During the year they had connected 219 new services with an equivalent of 11,975 lamps.

The Lighting Committee recommended that out of the profit of £4,751. 12s. 10d., the sum of £4,626. 12s. 10d. be placed to reserve or renewals fund account, and that the balance (£125) be transferred to District Fund. The accounts were approved and the Committee's recommendations adopted.

Bury (Lancs.)—The accounts of the electricity supply department for the year ended March last show capital expenditure £26,[illegible] making a total of £143,824, of which £23,520 has been repaid, and the sinking and reserve funds amount to £17,332.

Revenue was £19,215, working and general expenses were £9,108, profit was £10,107, plus £415 interest on investments. Capital charges were £8,574, leaving £1,948 net profit. £1,000 has been devoted to relief of rates and £656 placed to reserve. 4,180,280 units were generated, 65,393 supplied to public lamps and clocks (against 62,496 in previous year), 1,421,355 to tramways (against 1,771,718), and 2,527,499 (against 2,077,624) to private consumers by meter. The total maximum supply demanded was 2,022 kw.

The report of the borough electrical engineer (Mr. S. J. Watson) states that there were 607 consumers at March 31, with 117,551 (equivalent 8 c.p. lamps (increases of 42 and 10,238 during the year). The combined lighting and power load factor improved from 21·8 to 24 per cent., the tramway load factor decreased from 21·4 to 20·5 per cent. In January last it was decided to substitute groups of high c.p. metallic filament lamps for all the old open-type arc lamps for street lighting. 14 had been altered by March 31. The increase of hired and privately owned motors connected was 15 (296 H.P.), making a total of (2,802 H.P.). Generating costs per unit were 0·51d. (as in previous year), of which the cost of coal was 0·20d. (0·19d.), and total costs, including capital charges, were 1·01d. (0·92d.). Average prices received were 2·81d. (as in previous year) for private lighting, 1d. (against 1·[illegible]d. for public lighting, 0·744d. (0·765d.) for power, and 1d. (as in previous year) for tramway supply, the average for the total output being 1·14d. (1·14d.). Although a slight falling off in the units sold for lighting

Digitized by Google

pass has had to be recorded for two years through the use of metallic filament lamps, the past year shows an increase in that direction. A large reduction in consumption of current in the tramways has been effected by the use of car meters, and the income of the electricity department for the supply of current to the tramways is reduced by £1,416.

Cardiff.—At a recent meeting of the Tramways and Lighting Committee the engineer and manager (Mr. A. Ellis) reported on the principle of supplying electric power from the Roath station to the electric lighting department.

The accounts for the year to March 31 were also presented, and the report stated that the system had proved very satisfactory to both departments, showing that the principle of combining the load was a wise one. The total cost of generating at Roath was £16,726, and the total number of units generated was 10,604,299, an increase of 1,360,002 units on the year. The charge for supply to the lighting department was £6,352, an increase of £2,164. The lighting department benefited to the extent of obtaining energy at 0·72d. per unit, against 0·75d. If the power station was taken as a separate undertaking, and the tramways and lighting department as consumers at the same figure that the lighting department was being charged, the revenues from the tramways department to the power station would amount to £12,243. Deducting the cost of production for the whole of the output (£16,726), there was a surplus of £11,886 with which to pay capital charges, or 6 per cent. upon £20,000 capital, and 8 per cent. on a capital of £150,000; and as the capital expended upon the power station, lands, &c., was well under £20,000, it would be seen that the tramways were provided with ample funds from the lighting department with which to pay their proper proportion of such capital charges, and, further, that the tramways had everything to gain.

The chairman (Ald. CURTIS) said the report was highly satisfactory, and it was decided to enter it upon the minutes.

Coventry.—The total revenue for the year ended March 31 was £46,423 (including £13,561 from sale of current by meter, £29,840 from power supply and £800 for public lighting), against £36,920 in 1909-10.

Total works costs were £12,495 (0·378d. per unit) and total expenditure £34,187, against £11,380), the gross profit being £32,237 (against £25,540). With £10,238 brought forward and £23 bank interest, the available balance was £42,498. Interest absorbed £7,413 and sinking fund £7,932, a total of £15,822 (0·477d. per unit) for capital charges, and after paying property tax on interest (£458), placing £7,469 to reserve, applying £2,500 for relief of rates and paying bonus (£205) to employés, the balance £16,478 was carried forward.

This balance has now been applied as follows: £3,500 in aid of rates, £8,212 to meet cost of services, part cost of destructor and remaining value of plant superseded, &c., £1,150 for providing new workshop, tools, and other fittings and for replacing condensing plant for pumps, £3,000 to reserve, £237 as additional bonus to employés and £379 was carried forward. The total capital expended at March 31 was £271,201, an increase of £20,103 during the year. 8,822,170 units were generated; 7,732,024 were sold to private consumers and 211,913 supplied to public lamps (111 arc and 118 incandescent lamps); and the total maximum supply demanded was 4,769 kw. The total of works costs and capital charges was 0·855d. per unit.

Croydon.—The total revenue of the electricity department for the year ended March 31 was £61,489, including £52,884 net from sale of current for private lighting and traction, £6,964 from public lighting and £1,230 meter rent.

The total expenditure (£30,797) included £15,793 for generation, £733 for distribution, £1,638 public lamp maintenance, £2,575 rent, rates and taxes, £3,275 management expenses, and £4,774 for new services, meters and other charges. The gross profit was £30,691, and after paying £23,205 for sinking fund and interest on stock and loans and £1,149 for income tax, there was a net profit of £6,978, making, with £2,440 brought forward, a total of £19,388, of which £7,000 was placed to reserve and renewals fund, £12,015 voted to relief of rates, and the balance (£373) carried forward. The total capital expenditure is £351,251, an increase of £2,910 during the past year. 7,306,305 units were generated; 2,580,949 units were supplied to private consumers by meter (against 2,349,646), 2,787,244 supplied for traction (against 3,600,941), and 57,800 for public lighting (against 621,008). There are 420 arc and 425 incandescent lamps for street lighting (against 419 and 317), and the total maximum supply demanded was 3,613 kw. (against 3,319 kw.).

In the annual report of the borough electrical engineer (Mr. A. C. Cossor) it is stated that there was a considerable decrease in the output for public lighting and traction. Although the number of public lamps was increased, the cost of public lighting has been considerably reduced. The reduction in the energy sold for traction amounted to 813,697 units, representing £5,372 (or 20·6 per cent.). The saving by consumers changing over to metal filament lamps has continued, but in future will not have such a marked effect on sales. There was a satisfactory increase of 240,303 units sold for power and for heating and cooking. The average price per unit sold for general supply was 2·98d. per unit (against 3·01d.) and for total supply 1·92d. (against 2·25d.). There are 3,949 consumers (against 3,593), and the load factor was 21·13 per cent. (against 22·87 per cent.). In the last 10 years the reduction in the cost of producing electrical energy is equal to 46·06 per cent., or, on present output, £23,490 per annum.

Glasgow.—For the year ended May 31 the traffic receipts of the tramways department amounted to £946,021. 5s. 11d., an increase of £52,430. 4s. over 1909-10. The number of passengers carried was 237,967,307, an increase of 15,236,736.

There was a decrease of 2,409,941 in the total of penny fares, due to the fact that for the past four months two-stage fares have been in operation. The other stages, particularly halfpenny stages, showed increases. During the year a number of extensions were opened for traffic, including the Crow-road, Clincart-road, London-road and Kelvingrove-street routes, of a total length of six miles of route. The average track mileage open during year was 194¼ miles (single), an increase of 5¾ miles. The car-mileage was 21,704,237 miles, increase 730,221 miles; traffic receipts per car-mile were 10·461d., increase 0·236d.

Kingston-on-Thames.—The accounts of the electricity department for the year ended March 31 show capital expenditure £108,239, an increase of £2,795 (mainly on mains, transformers and services) during the year.

Revenue from sale of current by meter was £8,855 (against £8,520) and from public lighting £2,576 (against £1,929), meter rental, &c., making up a total of £11,983 (£10,907). Expenses were £6,555, or 2·137d. per unit sold (against £6,259, or 2·118d.), of which coal and other fuel represented £2,861, or 0·932d. per unit (against £2,546, or 0·859d.) Interest on loans and repayment of principal absorbed £6,621, or 2·158d. per unit (£6,292, or 2·125d.), and the debit balance was £1,193 (£1,644). There are 1,336 consumers (1,209) and the equivalent of 61,712 32-watt lamps is connected to the mains (55,814), of which 686 lamps were taking current through prepayment meters. 736,140 units were sold (710,704), including 579,652 to private consumers (574,610.)

In his report, Mr. J. E. Edgcome states that there is a further satisfactory increase in the number of motors connected and small motors have maintained their popularity. The number of radiators connected also shows a satisfactory increase. During the year 140 public incandescent lamps were erected. Several new consumers took advantage of the deferred payment system of wiring. The undertaking has suffered, though in a less degree than during the previous two or three years, from the continued substitution of metal filament lamps.

Lincoln.—In moving the minutes of the Electricity Works Committee at the Council meeting on Tuesday, the chairman (Mr. W. S. White) said that the accounts for the year ended March 31 had proved a record.

Mr. WHITE said that never before had they supplied so much current or carried so many passengers on their tramcars. The gross profit on the electricity department was £7,292, and deducting £3,969 for interest and sinking fund, the net profit was £3,323, an increase of £820 over 1909-10.

On the tramway undertaking the gross profit was £2,447. 10s. 11d., but after deducting £2,600 for repayment of loan and interest, the deficiency was £152. 16s. 3d., which had been provided for out of the profit on the electricity undertaking. The reserve fund amounted to £8,628, and although 1,649,090 passengers had been carried there had been no accident.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

Tenders are invited for the supply of 150 miles insulated wire and 5 miles of telegraph cable to the Postmaster-General's Department in Victoria. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to July 19 for the supply of insulators, telephones, copper and iron wire to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W. See an advertisement.

The Secretary of H.M. OFFICE OF WORKS invites tenders for providing and erecting at the South Kensington generating station complete surface-condensing plant, capable of dealing with 15,000 lb. of steam per hour, together with the necessary gantry and stanchions. Forms of tender and further information may be obtained at H.M. Office of Works, Engineering Division, 55, Whitehall, London, S.W., and tenders addressed to the Secretary must be delivered by 11 a.m. of Friday, June 30, at Storey's Gate, London, S.W.

The Commissioners of H.M. WORKS AND PUBLIC BUILDINGS also invite tenders for the supply of hemp and steel wire lift ropes during three years from July 1. Forms of tender, conditions of contract, &c., from the Storekeeper, H.M. Office of Works Stores, 12, Lambeth-Palace-road, London, S.E. Tenders by 11 a.m. of Monday, June 12, to the Secretary, H.M. Office of Works, Storey's Gate, London, S.W.

KETTERING Urban District Council invite tenders for the supply, delivery and erection at their electricity generating station of extension pipework, oil eliminating plant, &c. Copies of specification and general conditions of contract from the Clerk of the Council, Mr. John Bond, Council Offices, Kettering, where tenders must be delivered by June 19. Specifications, general conditions and draw-

Digitized by Google

ings can be seen at, but not obtained from, the consulting engineers, Messrs. Kennedy & Jenkin, 17, Victoria-street, Westminster, S.W.

The Council of the Metropolitan Borough of POPLAR invite tenders for supply, delivery and erection of one 3,000 kw. turbine alternator, complete with surface condensing plant; two water-tube boilers with superheaters, air heaters, fans and chimneys; one 30-ton electric overhead travelling crane and water softening plant. Specification and form of tender from the borough electrical engineer and manager (Mr. J. Horace Bowden), Glaucus-street, Bromley-by-Bow, E. Tenders to the town clerk (Mr. L. Potts), Council Offices, High-street, Poplar, London, E., by 10 a.m. Monday, June 19.

SWINDON Corporation require tenders by noon June 20 for the supply and erection of a 220-cell battery, an automatic reversible traction booster, a three-wire hand-regulated booster, and switchgear. Specifications, &c., from the Borough Electrical Engineer.

MANCHESTER Electricity Committee invite tenders for supply and erection of two water-tube boilers, superheaters, coal chutes, ash conveyors and fuel economisers. Tenders to Chairman of Committee, Town Hall, Manchester, by 27th inst.

SWANSEA Corporation require tenders by noon June 13 for the supply of c.c. motors and starting switches. Forms of tender, &c., from the Borough Electrical Engineer.

HESTON and ISLEWORTH Council require tenders by noon June 14 for supply of metallic filament lamps for street lighting. Particulars from the Engineer, Electricity Works, Hounslow.

STOCKPORT Electricity and Tramways Committees require tenders by noon June 14 for supply of overhead material, ironmongery, castings, oils, paints, waste, &c. Forms of tender from the Engineer.

HULL Education Committee require tenders by 10 a.m., June 20 for supply of electric fans and wiring and fitting for electric light at the new Sculcoates-lane school. Specification, from City Architect.

LONDON County Council require tenders by 11 a.m. July 4 for four electric traversers for car-sheds. Specification, &c., from the Clerk.

The Metropolitan Water and Sewerage Board, Albert-street, BRISBANE, Queensland, want tenders by noon Jan. 30 next for supply and erection, of one, two or three complete units, each consisting of power generating plant and pump or pumps to lift not less than 6,000,000 gallons per day. Particulars from the Secretary.

Tenders are invited up to July 25 for the supply of 12 sections of a branching multiple magneto lamp signalling switchboard, &c., or one automatic or semi-automatic switchboard, &c., and up to June 27 for supply of 1,400 protectors for use on main distributing frame at magneto exchanges to the Postmaster-General's Department, VICTORIA. Tender forms, &c., from 72, Victoria-street, London, S.W.

The Town Clerk, WANGANUI, N.Z., will receive tenders until July 12 for supply of generating plant, gas-producing plant and battery and booster for the Corporation tramways. Specification can be seen at 73, Basinghall-street, London, E.C. Local representation is necessary.

CALARSHI (Roumania) municipal authorities invite tenders for a 35 years' concession for electricity supply in Calarshi. Provisional deposit of £480 will be required with tenders.

The Chairman of the Board of Control, WINNIPEG (Canada), will receive tenders until 11 a.m. July 3 for supply and installation of a police patrol telegraph system.

NAPLES Municipal Authorities require tenders by July 9 for supply and installation of the following plant in connection with the supply of electric power to Naples from the river Volturno:

1. Tubing and accessories for harnessing the water at rate of 7,000 litres a second and for the fall of 190 meters; upset price 702,900 lire (£28,116.)

2. Machinery and apparatus for hydro-electric power station, transmission line (about 57 miles), and transforming station; upset price 1,000,000 Frs (£40,000.)

Tenders to Presidente del Consiglio Generale dell' Ente Autonomo Volturno, Naples.

Manufacturers who are prepared to supply 600 km. (372 miles) copper wire 8 mm. dia. are invited to communicate with the Direzione dell' Ente Autonomo Volturno, Naples, who after two months from April 10 will send invitations to tender to firms whom they consider suitable.

Conditions of tender, &c. (in Italian) may be seen at 73, Basinghall-street, London, E.C.

The Egyptian Ministry of Public Works, CAIRO, will receive tenders until noon June 15 for supply and erection of an electric pumping installation with electric motors, switchboards, &c. Stamped paper for tenders can be obtained from Mr. A. L. Webb, C.M.G., Queen Anne's Chambers, London, S.W.

The Turkish Ministry of War, CONSTANTINOPLE, require tenders by June 26 for electric accumulators for the fez factory at Eyouband the tailoring workshop at the Ahir Capou. Particulars from the Administration Générale des Fournitures, at the Ministry of War, Constantinople.

TENDERS RECEIVED AND ACCEPTED.

Siemens Bros. Dynamo Works (Ltd.) have obtained the contract for the supply of "Tantalum" and "Onewatt" metal filament lamps of various voltages and candle powers, for the G.P.O. for the ensuing six months.

Blackburn Council have accepted the tender of the British Westinghouse Co. for the supply of a 2,000 kw. turbo-generator and two rotary converters.

York Electricity Committee have accepted the tender of the Tudor Accumulator Co. for replating the battery and supplying an automatic reversible booster, switchboard, cables, &c., at £1,625.

Caversham Council have accepted the tender of the Reading Electric Supply Co. for public lighting for 10 years.

The terms are as follows: (*a*) For 213 lanterns each equipped with two 55-watt lamps, alight till 11 p.m., £1. 17s. 3d. per lamp per annum; (*b*) 34 lanterns each with two 55-watt lamps till 11 a.m. from April 1 to Sept. 30, and all night from Oct. 1 to March 31, £2. 3s. 6d.; (*c*) four lanterns each with two 80-watt lamps till 11 p.m. from April 1 to Sept. 30, and all night from Oct. 1 to March 31, £2. 13s.; (*d*) seven lanterns each with two 80-watt lamps, alight all night throughout year, £3. 2s. 6d. per lamp per annum.

Leyton Council have accepted the following tenders:—

Mordey, Fricker & Co., for the annual supply of prepayment meters; Measures Bros., for wrought steel work for additional flue dampers (£27); Cottis & Sons, c.i. work for ditto (£17); Tudor Accumulator Co., battery to test tramway meters, £29.

Croydon Corporation have placed an order with Johnson & Phillips for 51 magazine arc lamps.

Derby Council have accepted the tender of John Spencer (Ltd.) for 35 trolley standards at £187. 5s.

Marylebone (London) Council have accepted the tender of W. Geipel & Co. for annual supply of arc lamp carbons.

BUSINESS NOTICES.

After the 10th inst. the registered offices of Vickers Limited will be Vickers House, Broadway, Westminster, S.W. Telephone 10110 Gerrard (Nat., 8 lines). The telegraphic address will remain "Vickers London."

Messrs. E. M. Evans & Sons, electric lighting and power engineers, have removed to 1 and 5, Lever-street, Manchester. Telephone, 4,250 City.

John McIvor Lambie and Chas. Robt. Wrigley, electrical engineers, 116, City-road, London, E.C., have dissolved partnership.

Sales by Auction.—Messrs. Fuller, Horsey, Sons & Cassell have been instructed to sell by auction at H.M. Dockyard, Devonport, on Tuesday, July 11 and following days some old and surplus stores, including 180 tons scrap brass and mixed metal, 10 tons manganese bronze, 8 tons lead skimmings and packing, 900 tons mild scrap steel, 900 tons scrap iron, 30 tons zinc ashes and bottoms, &c.; also 65 tons electric cable, electrical gear and various stores, 4 motors, gas and steam engines, overhead traveller, crane, pumps, machine tools, lamps, furniture and fittings, &c. May be viewed three working days prior to and on mornings of sale, and catalogues (6d each) had at the Dockyard, or of the Auctioneers, 11, Billiter-square, London, E.C., and 100, King-street, Manchester. See also an advertisement.

Messrs. Horne & Co., 35, Old Queen-street, Westminster, S.W., will sell by auction at the Royal Arsenal, Woolwich, at 11 a.m. on Tuesday, June 20, unserviceable and obsolete stores, including iron and steel scrap, brass, copper, gunmetal, lead and tin alloy, zinc &c., electric cable, tools, pumps, electrical instruments, lamps, &c. May be viewed at the Royal Arsenal, Woolwich, on Friday and Monday, prior to and on morning of sale. Catalogues at the War Office, Whitehall, the Ordnance Office, Tower, and the Ordnance Office, Royal Arsenal, Woolwich. See also an advertisement.

Patent Development.—The proprietor of British patent No. 11,861 1905, relating to "Improvements in galvanic battery plates," desires to make arrangements for developing and working same in this country. Applications to Messrs. W. P. Thompson & Co., patent agents, 285, High Holborn, London, W.C.

The proprietors of the following patents also desire to enter into negotiations for the grant of licences to manufacture under royalty in Great Britain;—

No. 18,245/1907, relating to "Electrically-driven vehicles."
No. 17,852/1908, relating to "Continuous-current motors."
Nos. 24,211 and 24,212/1908, relating to "Incandescent electric lamps."

Inquiries to Messrs. Carpmael & Co., Patent Agents, 24, Southampton buildings, London, W.C.

BANKRUPTCIES, LIQUIDATIONS, &c.

The trustee in the bankruptcy of Alfd. E. Felgate and Wm. Storey, electrical engineers, 10, Queen Victoria-street, Reading, has been released.

A first and final dividend of 10¾d. will be payable on June 12 at the offices of Messrs. Brittain & Brittain, North-Eastern Bank-chambers, Stockton-on-Tees, to creditors of Ernest F. Jones, electrical engineer, &c., 132, York-road, West Hartlepool.

An application for the discharge of Geo. Montague Sellick, electrical accessories manufacturer, 466, Romford-road, London, E., will be heard on June 27 at Bankruptcy Buildings, London, W.C.

Creditors of Arc Lamps (Ltd.) (in liq.) must send particulars of claims, &c., to the liquidators, H. B. Clark and G. E. Corfield, 3 and 5, Cowan-court, Old Broad-street, London, E.C., by July 7.

Improved Electric Traction (Ltd.) is being wound up voluntarily. Claims to the liquidator, Mr. H. M. Gower, 428, Birkbeck Bank-chambers, London, W.C., by July 15. A meeting of creditors will be held at Mr. Gower's offices on June 15.

A meeting to receive an account of the winding-up of the Telewater Syndicate (Ltd.) will be held on July 4 at 3, London Wall-buildings, London, E.C.

COMPANIES' MEETINGS AND REPORTS.

Callender's Cable & Construction Co. (Ltd.)

The annual general meeting was held yesterday (Thursday), Mr. Hy. Deane presiding.

The CHAIRMAN referred with regret to the deaths of the secretary, Mr. Harrison, and one of the founders of the company, Mr. D. P. McEuen. As stated in the report (which was abstracted in our last issue) the undertaking of the Uxbridge & District Electric Supply Co. was acquired during the year, and debenture stock had been issued to cover the cost. He also gave particulars of the various items in the accounts. Anchor Cable Co.'s shares were valued at £57,500 (as last year). St. Helens Cable & Rubber Co. (against this £35,280 in shares and debentures as before, £38,376 (£38,829), shares and investments in other companies £38,800 (£28,611), the total assets being £1,124,133 (£1,049,422). Profit for the year, after deducting all charges on manufacturing accounts and contracts, including salaries, &c., at Erith, were £93,204 (£98,135). After providing £8,217 for depreciation and paying interest on the debentures and dividend on preference shares, it was proposed to dispose of the balance of £66,323 (£68,422) by payment of the dividends and bonus shown in the report, and carrying forward £40,073 (£42,202).

Mr. T. O. CALLENDER (managing director) said that during 1910 the position of the company's business, and he believed of all heavy construction businesses in this country, was bad. He was afraid they had seen any of the alleged boom in trade, and others with whom he had discussed the outlook were of his opinion, that the boom had not reached the engineering world. The signs observed at the end of last year of a lightening in the dark cloud had unfortunately passed away, and again they had been in the doldrums, absolutely nothing being done. They had, however, managed to maintain, and to improve upon, the position they had in the previous year. Since Easter there had been a distinct improvement, and the factories at Pontypool Leigh were busy and running full time. The position of the electric supply and power companies had materially improved during the last few years. They were getting over their "childhood's maladies." The overhead electrical supply in this country was settling down to a sound business on the lines of their competitors, the gas companies, and, he might say the railway companies. They were now finding in every case that the anticipations they had when they entered the power business some years ago were being fulfilled, and he hoped the company would, therefore, get better orders from the supply companies than they had in the past. They had pushed energetically for work, and one could hardly enter a port without seeing power drums. The idea in some people's minds that English firms were remiss in pushing trade abroad might be true in some instances, but his experience was that foreign trade could not be got in the way newspaper critics would lead one to believe. They had a battle to fight. A few days ago the engineer of a large electric power who was over here told him that a certain order had not been given to Callender's Co. because the German Ambassador intervened and put pressure to bear, and that led to the order being placed in Germany. He (Mr. Callender) and others had discussed the necessity for the formation of some bank or financial association to put them into a position to fight those heavy influences which were now acting against them. Owing to these days (it might be this year or next) the board would ask shareholders to assist them in backing up such an institution, which would be the only way in which British trade could be secured in certain portions of the world. The last field the company had entered was South Africa, and they had already most important contracts. They were strengthening their position, and they were getting some of the trade that was going. In reply to questions by shareholders, he said they had written a very large amount off plant and machinery, and he was satisfied that the amount written off this year was ample. He did not think it advisable to state the value of land separately. They had had some of their ideas and schemes seriously damaged by having brought them too prominently before the shareholders, and at the same time before their competitors. The shares held in other companies had been amply depreciated where necessary.

The report and accounts were adopted and the dividends and bonus approved.

ALUMINIUM CORPN. (LTD.)—The directors' report from the date of incorporation (Dec. 14, 1909) to Dec. 31, 1910, states that aluminium is now being made on a commercial scale, the metal produced being of a high grade. The works are being extended to their full capacity, and it is anticipated that the output will find a ready market. The dam at Eigiau Lake, Dolgarrog, is on the point of completion, the Cowlyd Leet has been put into operation, and the necessary water rights of the Dulyn river have been acquired. The serious problem of traffic in connection with the supply of raw materials for the Dolgarrog works and the dispatch of the manufactured metal has been solved. The company's liability in connection with the shares of the Bauxite Refining Co. has been paid up in full, enabling the Bauxite works to be completed to a capacity sufficient to supply the corporation with alumina of first quality. It is proposed to convert the preference shares into preference stock, and the ordinary shares are to be sub-divided and converted into preference and ordinary stock.

BRITISH ELECTRIC TRACTION CO. (LTD.)—The directors in their report for the year ended March 31, state that there is a general improvement in the position and prospects of the Company. The traffic receipts of the associated companies for year show a marked improvement, which promises to be maintained in the current year. The net profits of these companies show a substantial increase for 1910. For the most part, however, these increased profits have been added to reserve and renewal funds, or have been otherwise applied in strengthening the position of the companies. The profit of the B. E. T. Co. from this source has, therefore, not increased by so large an amount as would otherwise have been the case. No increase of dividend is recommended by the directors for the past year, but they recommend placing £25,000 to reserve out of profits, compared with £15,000. The opportunities of promoting new electrical undertakings in this country with a prospect of reasonable profit under present conditions continue to be restricted, but whenever the conditions justify extensions of electrical business in this country the resources of the Company will enable it to participate in them. Meanwhile, the directors hope that some of the foreign enterprises which have engaged their attention will mature during the current year. Further successful efforts have been made to reduce expenses, but in view of the large economies already effected the reductions cannot now be carried much further. The directors consider the time has now arrived when the interests of the company will best be served by a re-organisation of the capital dealing with the arrears of dividend on the preference shares, and equitably adjusting the relations between the two classes of shares. The directors will place their proposals before the shareholders at an early date. In March, 1910, the reserve was £633,581. 17s. 3d. This account has since been debited with £6,318. 19s. 7d. loss on sale of Consols and credited with £1,675. 4s. 8d. net profit on sale of other investments, and adding £12,393. 9s. 9d. (the difference between the nominal value and purchase price of certain debenture stock); the reserve at March 31, 1911 stands at £641,331. 12s. 1d. It will be further increased by £25,000 proposed to be transferred out of the profits of the year. In addition, reserves amounting to £4,052. 14s. 7d. have been made out of profits of the year against loss and depreciation of specific assets. The total of these reserves is £63,787. 0s. 7d. The associated companies have created depreciation and other reserve funds of their own, which amounted at Dec. 31, 1910 (including balances carried forward), to £1,228,127. During the year the directors sold part of the large amount of Consols held by the company and re-invested the proceeds in India 2½ per cent. stock and other securities yielding a larger return than is obtainable from Consols. The item, Investments and Undertakings stands at £5,204,667. 8s. 9d., and consists of shares and debentures in associated tramway, electricity supply, manufacturing and other companies, Consols and sundry securities and undertakings, of which debentures in various companies of the nominal value of £563,950 stand in the books at £527,596. 4s. 8d. and shares in various companies of the nominal value of £4,523,490. 18s. 4d. stand at £4,360,299. 9s. 6d. The year's net profit, after applying £5,947. 5s. 5d. to writing down expenditure on Acts of Parliament, &c., and after reserving £4,052. 14s. 7d. against depreciation of undertakings worked by the company, buildings and freehold land, and doubtful debts, is £139,512. 19s. 10d., to which must be added £14,067. 9s. 6d. brought forward, making a total of £153,580. 9s. 4d. After deducting interest on the 5 per cent. perpetual debenture stock and the 4½ per cent. second debenture stock for the year, amounting to £93,533. 2s. 7d., there remains a balance of £60,047. 6s. 9d., out of which it is proposed to pay a dividend of 3s. per share on the preference shares, amounting to £24,215. 11s., and to transfer £25,000 to reserve, leaving a net balance of £10,831. 15s. 9d. to be carried forward. This dividend will bring the payment of the full dividend on the 6 per cent. cumulative preference shares to Sept. 30, 1908, and the reserve will be increased from £641,331. 12s. 1d. to £666,331 12s. 1d. The yield for the past year on the total investments and undertakings standing in the books at £5,204,667 was 2·7 per cent., compared with 2·63 per cent. for the preceding year on £4,997,845. Since March 31 last Mr. E. Garcke has acted as sole managing director. Mr. C. Shirreff Hilton and Mr. W. L. Madgen have resigned the positions of joint managing directors, but they remain directors of the Company, and they have agreed to continue to act as chairmen and directors of various associated

Digitized by Google

companies and to perform other special services. Mr. George Cornwallis-West has been appointed a director of the Company. The members of the board who act as chairmen or directors of associated companies receive special remuneration therefore in addition to the remuneration paid to them for their ordinary services as directors of the B. E. T. Co., but they pay to that company all fees received by them from the associated companies. Sir Charles-Rivers Wilson proposes to vacate the position of chairman of the board after the general meeting, but will remain a director, and Mr. E. Garcke has been appointed to succeed him as chairman.

BRUSH ELECTRICAL ENGINEERING CO. (LTD.)—At the meeting on Wednesday the Chairman (Mr. E. Garcke) said that the results of the business for the past year were better than for the preceding year. The gross profits were £28,159, compared with £14,349. After paying debenture interest, the loss was £10,780 against a loss of £21,230. The causes of the loss were insufficient volume of business and consequent keenness of competition for such orders as were placed, resulting in unremunerative prices. There was probably no business or trade in which the expenses were relatively so heavy, the responsibility so great and the reward so insignificant as in the electrical industry. The conditions were constantly changing—new inventions and discoveries succeeding each other with disconcerting rapidity, and making it almost impossible, speaking generally, to standardise or to settle down to economical production of manufactures in large quantities. Those conditions necessitated the retention of experts who were specially skilled in their various departments. The establishment expenses of the business were, therefore, always high, and could not, without crippling the organisation, be reduced below a certain minimum, whether trade be good or bad. The new Invalidity and Unemployment Bill would probably increase their expenses by over £2,000 per annum, a heavy charge for a business not clearing its charges. During the last few months there had been a decided revival of business in the electrical engineering industry. Many of the central power stations had now recovered the temporary loss of load which they had to face owing to the general adoption of the current-saving metal filament lamp, and had found it necessary to place orders for additional plant. Of these orders they had secured their share, and it was gratifying that their turbo-generators and other power house plant were held in such excellent reputation. They entered the current year with a much larger volume of unexecuted orders in the factory than was the case in the previous year, and that circumstance, coupled with the fact that the new orders secured this year were above the average, justified the hope that they might this year turn the corner. The directors proposed to formulate a scheme for the reorganisation of the capital.

CAPE TOWN CONSOLIDATED TRAMWAYS & LAND CO. (LTD.)—The accounts for 1910 show a balance of £1,045. 11s. 1d. to debit of profit and loss account, which, added to balance brought forward (£2,169. 16s. 1d.), makes the total debit £3,215. 7s. 2d. to be carried forward. The result of the operations of the Camps Bay tramways shows a loss on working of £375. 18s., compared with a loss for 1909 of £1,559. 13s. 4d., and of £2,232. 11s. 3d. in 1908. A continued further improvement is anticipated.

DIESEL ENGINE CO. (LTD.)—The report for the year ended March 31 states that the gross profit was £12,376 (£11,564 in 1910). The net profit was £2,147. The total at credit of profit and loss account is £5,240. Out of this the directors recommend payment of the preference dividend (absorbing £938) and carrying forward £4,302. As the expenses of further pioneering work are likely to be heavy, it has been deemed prudent not to pay an ordinary dividend. Mr. S. Furness, M.P., has joined the board.

PEEL-CONNER TELEPHONE WORKS (LTD.)—The directors' report states that the net profit from the commencement of the working of the company, after writing off preliminary expenses (£527. 5s. 3d.) and placing £2,151. 7s. 1d. to reserve, was £7,276. 11s. 3d. This balance will enable the directors to pay the full preference dividend at the rate of 5 per cent. from date of issue (£6,956. 9s. 5d.), and to carry forward £320. 1s. 10d. The directors are gratified with the result of the first year's trading. The difficulties of training efficient labour are gradually being overcome. A number of contracts recently obtained ensure full employment for the works for a considerable time.

UNITED ELECTRIC TRAMWAYS OF MONTEVIDEO (LTD.)—The gross receipts for the year ended Oct. 31, 1910, were $1,315,955, against $1,190,310 in the previous year; the operating expenses $731,994, against $694,588; and the net receipts $583,961 against $495,722. 32,474,355 passengers were carried, against 29,293,804, and 6,185,737 car-miles run, against 6,282,240. The extensions to the main car and store sheds and the enlargement of the company's hotel at Pocitos have been nearly completed. The extension of the lines to the suburb of Maldonado (approximately 3 miles) is in course of construction and is expected to be open for public service during the next few months. During the past month there has been a general strike in Montevideo, including the tramway employées. Owing to the absence of adequate protection for the men who were willing to work, the services were entirely suspended for several days. The terms upon which the strike has been ended will involve a permanent additional charge upon future revenue. £2,555 has been set aside for debenture stock redemption fund and £20,000 transferred to renewals and contingency account. Interim dividends of 6 per cent. on the preference and ordinary shares for the half-year to Sept. 30, 1910, have been paid and the directors now recommend payment of a dividend at the rate of 6 per cent. per annum (less tax) on the preference shares and at the rate of 8 per cent. per annum (making 7 per cent. for year), leaving £13,754. 19s. 8d. to be carried forward.

VICTORIA FALLS & TRANSVAAL POWER CO. (LTD.)—In the directors' report for the year ended Dec. 31 it is stated that during 1911 the balance of the preference shares has been issued, bringing the total issued capital up to £3,000,000. The total share and debenture capital at the date of the report stood at £4,700,000. An agreement has been entered into with the Dresdner Bank and the Deutsche Bank to take up a further £1,000,000 5 per cent. first mortgage debentures, leaving a balance of £300,000 out of the authorised amount of £3,000,000. The year's business has resulted in a profit of £157,749, to which is added the balance of £135,398 from 1909. After providing for debenture interest, income tax, depreciation for 1907, 1908 and 1909 (£75,887) and for the year 1910 (£38,964), the balance is £95,747, out of which the directors declared a preference dividend at the rate of 6 per cent. per annum on the amount paid on the shares, from Jan. 1 to Oct. 14, 1909. These payments will absorb £58,347, leaving £37,400 to be carried forward. The profit shown in the accounts has been secured from sale of power from the Brakpan and Simmer Pan stations only. An agreement has been entered into between the company and the Rand Mines Power Supply Co. by which the entire management of the latter is placed in the hands of this company.

NEW COMPANIES REGISTERED.

BIRMINGHAM MICA CO. (LTD.) (116,048.)—Reg. May 26, capital £2,000 in £1 shares, to take over the business of workers of and dealers in mica and other insulating materials carried on as the Birmingham Mica Co. Private company. Reg. office, 250, Icknield-street, Birmingham.

T. CLEMMONS & CO. (LTD.) (116,092.)—Reg. May 29, capital £5,000 in £1 shares, to take over the business of aluminium goods and castings manufacturers carried on by T. Clemmons & Co. Private company. First directors, H. W. Tomlinson and M. B. Wild.

SAMUEL HARTFORD & CO. (LTD.) (116,148.)—Reg. May 31, capital £10,000 in £1 shares, to carry on the business of manufacturers of and dealers in wires, cables and lines of all kinds, electricians, electrical engineers and contractors, &c., and to adopt agreements with S. Hartford and D. Woolfright. Private company. First directors, S. Hartford and P. Woolfright (both permanent).

WOODHOUSE STEEL CASING CO. (LTD.) (116,097.)—Reg. May 29, capital £6,000 in 4,000 6 per cent. participating non-cumulative A preference shares of £1 each, and 4,000 A ordinary shares of 10s. each, to take over the business of the Woodhouse Steel Casing Co., and to carry on the business of manufacturers and sellers of electrical appliances, engineers, founders, &c. Private company. First directors, A. E. Woodhouse and W. W. Little, both permanent. Reg. office, Craven House, Kingsway, London, W.C.

CITY NOTES.

NOTES.

End of the Metal Filament Depression.

It is now becoming evident that the pessimistic opinions held a year or two ago by some central station engineers as to the effect of metal filament lamps on the prospects of the supply industry are not likely to be justified. Indeed, many reports show that considerable progress is again being made in private lighting, and the normal growth of the output seems likely to be resumed. The annual report of Mr. S. J. WATSON, borough electrical engineer at Bury, may be cited as a case in point. The sales for private lighting, after a slight falling off during the last two years, have for the 12 months just ended increased by no less than 12·3 per cent., whilst 42 new consumers have been obtained, a larger number than during any of the last seven years. When it is also mentioned that the output for power has increased by 24 per cent., a very satisfactory state of affairs might be anticipated. The introduction of meters on the tramcars, however, has resulted in the revenue received from the sale of current to the tramways being £1,406 less than in the previous year, the output for traction having declined by no less than 19·7 per cent. Whilst this result is, of course, unfortunate for the electricity department, the economy introduced by adopting meters should encourage other tramway undertakings to experiment in this direction. Attention may also be called to the fact that Mr. WATSON anticipates a considerable increase in the power load when the new three-phase station now under construction is completed. In erecting this station Bury is following the policy which has proved most satisfactory in other towns.

The Advancement of the Telephone.

AT the annual meeting of the Peel-Conner Telephone Works (Ltd.), this week, the chairman of the Company, Mr. HUGO HIRST, threw out the suggestion that when the General Post Office have the telephones in their hands they should work along similar lines to an electricity supply undertaking. In other words the Post Office should bring their lines to a house, and the installation of the telephone, on whatever system might be necessary, should be carried out by independent contractors engaged by the owner or occupier of the premises. Mr. HIRST pointed out that a staff of inspectors in the service of the General Post Office would be necessary, but under such a system the Post Office would have the advantage of the services and enterprise of the whole electrical trade for obtaining subscribers and for extending their business.

AT first sight this seems to be an excellent suggestion, but we fear that it would not be altogether feasible, because there is a very distinct difference between a telephone service and one for electricity supply. If anything goes wrong with the telephone installation the subscriber turns instinctively to the National Telephone Co. or the General Post Office, as the case may be, but if the installation were carried out by a contractor the telephone authority might very well feel disinclined to accept the responsibility of putting right any subsequent troubles free of charge. The subscriber, on his part, would find it very inconvenient to call in a contractor to put right anything that might be wrong. Apart from this, however, we need scarcely point out that the connecting up of a telephone service is by no means so simple a matter as connecting up a service for

Digitized by Google

light or power. In the case of the telephone service a very definite connection has to be made to the exchange before messages can be handled, and thus it is more necessary for the telephone authority to have the matter in hand than it is for the supply authority in the case of electric lighting or power, where it is merely a question of connecting up to mains so long as the station is not overloaded. Nevertheless, we fully sympathise with Mr. HIRST in his desire to popularise the telephone, and we hope that all that can be done without making matters really more complicated when the General Post Office enter into possession of the field will be done in due course.

Strenuous Opposition.

STRIKING testimony of the anxiety with which gas companies regard the progress of electric supply undertakings, and of the determination of the companies to offer still greater opposition to the development of these undertakings, is afforded by the recent action of the Wrexham Gas Co. A little more than two months ago we referred to the petty complaints of the chairman of the Company as to the canvassing by the electricity department of the Gas Company's customers. Not content with protests, however, the Company recently strenuously opposed, at a Local Government Board inquiry, the Council's application for further loans for extensions of the electricity undertaking. The counsel for the opposition undoubtedly put the matter in a nutshell when he stated that his clients' case was "that the electricity concern was going ahead too fast." Such candour is to be welcomed. The Gas Company are particularly disturbed because the Council are proposing to convert more gas lamps to electric lighting; and as a reply to the electrical engineer's statement that he could light and maintain electric lamps of 50 c.p. for 14s. per lamp less than the cost of gas lighting, the Company stated that the gas lamps in Wrexham each gave 140 c.p. We understand, however, that the makers of these particular lamps only claim 75 c.p. per lamp, doubtless under the most favourable conditions, so that the Company's statement seems rather a figure of speech than anything else; but perhaps we ought not to expect much more than 50 per cent. accuracy under these circumstances.

Wanted—A Policy.

THE inquiry just referred to has drawn attention to the absence of any definite policy on the part of the Local Government Board in regard to certain aspects of municipal trading in general and electricity supply in particular. It is in the highest degree desirable that the Board's inspectors should be animated by a uniform policy, but this appears to be far from the actual state of affairs. Thus, when Mr. Ross HOOPER held an inquiry at Wrexham on the occasion of a previous application by the Council for a loan for electricity supply extensions, he strongly advised that all profits made by the electricity undertaking should be allocated to a reserve fund. This advice, which we think was decidedly sound, has been followed by the Council; but now Mr. T. C EKIN, at the recent inquiry, wants to know why certain profits have been paid to the reserve fund and not to the relief of the rates. The confusion which must result from such conflicting advice on the part of Government officials will tend to make municipal authorities regard Local Government Board inquiries with even less favour than in the past, whilst the claims of certain sections of ratepayers that all profits should be handed over for the relief of the rates will be strengthened. That a reserve fund is essential for any electricity undertaking is opportunely emphasised by the Inspector's report on the recent inquiry at York referred to elsewhere in this issue. It is therefore to be regretted that another of the Board's officials should have said anything that can be regarded as discounting the present policy in providing for unforeseen expenditure.

Annual Report of the Chief Inspector of Factories and Workshops.—The annual report for the year 1910 of Dr. B. A. Whitelegge, C.B., H.M. Chief Inspector of Factories, was issued this week. In their report in February last the Accidents Committee regarded the increase in the number of reported accidents up to 1907 as almost entirely due to improvement in reporting, which since that date has been less marked. The statistics given in the present report show that the total number of accidents in 1910 was 129,550, as against 117,500 in 1909, 122,154 in 1908 and 124,325 in 1907. The increase shown in 1910 is attributed by Dr. Whitelegge to improved trade and more employment. The number of accidents attributable to electrical apparatus shows little change, notwithstanding the increased use of electricity for light and power. In summarising the sectional reports, Mr. H. M. Robinson, deputy Chief Inspector, says a further advance in the use of electrical energy for power purposes in factories has again to be recorded, as is shown by the returns issued by THE ELECTRICIAN. Owing to the technical nature of the requirements set out in the revised regulations for the use of electricity, it has been found that occupiers are inclined to await instructions from the inspector before taking steps to comply with these regulations, but the explanatory memorandum of Mr. G. Scott Ram, H.M. Electrical Inspector of Factories, has proved of great service. We hope to give in our next issue an abstract of Mr. Ram's report.

Enlargement of the Cos Cob Power Station of the New Haven Railroad.—According to the "Electric Railway Journal," the New York, New Haven & Hartford Railroad is more than doubling the size of its Cos Cob power station. Orders have been placed for four Westinghouse-Parsons single phase turbo-generators, each of 4,000 kw. capacity. These will supply energy at an 80 per cent. power factor, thus increasing the generating capacity of the station from 12,000 kw to 28,000 kw. The present boiler equipment will be increased proportionately, and the coal-handling plant will be rearranged and enlarged.

Large Telephone Installation.—In the McAlpin Hotel which is now being built in New York, the telephone installation will consist of 100 trunk lines and 1,800 stations. It is estimated that there will be transmitted from these stations 500,000 messages annually at a service cost of £5,666. The main telephone switchboard will contain 16 regular operating positions. There will be three sub-switchboards, as follows: One two-position switchboard with 17 booths in the main corridor; one with 16 stations in the engineering department and one with 12 extensions for the use of the office staff. There will also be a complete telautographic equipment of 1 instruments.

Cable Interruptions.

	Date of Interruption
Assab—Perim	July 8, 1909
Malta—Tripoli	April 20, 1910

New Electric Travelling Facilities.—The British Electrical Federation, which comprises numerous tramway and electric supply undertakings in Greater London and the provinces, has been making inquiries extending over some months regarding "trackless trolley" methods of construction. The method most favoured is that known as the Bremen system (see THE ELECTRICIAN, April 28th, 1911, p. 93) which was first put into use in that city. It is hoped that in this manner improved traffic facilities may be provided in rural and extra-suburban districts, where the greater expense of laying tramway tracks would not be justified.

Electric Locomotives for the Panama Canal.—A note in "The Engineer" states that tenders have been invited for electric locomotives of a special type for service on the Panama Canal. They will run on a rack railway, and will be employed for towing vessels through the waterway. In the design formulated by the Isthmian Commission these towing locomotives are to be constructed in three sections, of which the front and rear are to be mounted on rigid four-wheel trucks, each driven by an independent motor, while the middle section is connected to the two tractive elements by universal joints, and is to be equipped with a slip-drum towing windlass and hawser, so that the line may be veered and hauled at pleasure without any motion of the locomotive along the track. The current for the operation of the locomotives will be taken from underground circuits. The maximum pull on the tow line is fixed at 25 tons, at which force a friction coupling will relieve further stress. The central racks are to be provided only on the towing tracks and inclines. On the level portion of the return tracks the locomotives will run by friction on the side rails as on an ordinary electric railway.

100,000 Volts Transmission Line in Canada.—The Canadian "Electrical News" states that work has just been commenced by the Shawinigan Water & Power Co. on the construction of an electrical transmission line from Shawinigan Falls to Montreal, a distance of about 85 miles. This line will consist of two three-phase circuits. A new receiving and distributing station is now being erected by the Company near their other east-end station at Maisonneuve. This will be the Montreal terminal of the new line. The cable will be worked at 100,000 volts and be capable of carrying the equivalent of 50,000 H.P. This load will constitute the first instalment of a contract made by the Shawinigan Company to furnish the Montreal Light, Heat & Power Co. with 60,000 H.P. The new line between Shawinigan and Montreal will follow closely the route of the Canadian Pacific Railway between those points, and for the greater part of the distance will be about 10 miles from the line built a few years ago, which lies close to the Canadian Northern Railway. The construction work will be done entirely by the Company's own staff. When this line is completed the Company will be ready to build another line to furnish the balance of the power required by the Montreal Light, Heat & Power Co.

Protecting Gas Pipes against Electrolysis.—In the correspondence columns of a recent issue of the "Electrical World" Mr. J. L. Fitzhugh describes how, after a number of experiments to protect its service pipes against electrolysis, the Laclede Gas Co., of St. Louis, is now covering its wrought-iron piping with layers of pitch and paper. This method seems to be proving successful. The wrought-iron pipe is first coated with a tar-and-pitch mixture, heated and thinned sufficiently to flow easily, and on to this a 4 in. paper ribbon is wrapped spirally, its edges overlapping. This paper covering is then tar-painted and again wrapped with paper, the process being repeated until four successive coats of tar and paper have been applied. Pieces of pipe thus insulated have been placed in the ground under conditions distinctly favourable to electrolysis, together with other lengths not so treated, and after being taken up at the end of two years the unprotected pipes were badly pitted and almost completely destroyed, while the insulated piping was virtually in the same condition as when laid. It is believed that pipes so treated will have their life at least doubled. Only service runs are being so treated, the cast-iron mains being less subject to corrosion and electrolysis than the service pipes. The tar and paper coating is very hard when cooled, and the pipe lengths need be handled with no more care than bare pipe.

Wireless Telegraphy and Aeroplanes.—At a meeting of the Royal Institution last week Mr. T. Thorne Baker delivered a lecture on this subject. The airship was, he said, easy to deal with on account of its comparatively large carrying capacity which enabled accumulators or a small dynamo to be carried for supplying electrical energy to the wireless apparatus. In the case of the aeroplane, however, weight was an all-important factor. Mr. Farman had obtained satisfactory results with his biplane by using two trailing aerials, each one consisting of rather thin wire about 100 metres in length. A similar Hertz arrangement had been applied by the lecturer (*see* THE ELECTRICIAN, March 17, 1911, p. 902) to a Bristol biplane, no loose wires being used. In receiving wireless messages on aeroplanes the chief difficulty was noise. Visible methods of receiving the wireless message had therefore to be adopted. Vibration was also a difficulty if the ordinary coherer was used, and an anti-vibration holder might be necessary. In the case of the Beta military airship wireless signals had been transmitted a distance of 50 miles. One of the most useful advances in wireless work was the conduction wireless telephone of Mr. A. W. Sharman; and remarkable possibilities were suggested by the attempt to employ the surface of water in place of the ether as a transmitting medium.

The Direct Measurement of the Attenuation and Characteristic of Telephone Lines.—The direct measurement of the attenuation and characteristic of telephone lines is a subject of the greatest interest, for all the phenomena which occur on such lines depend on these two factors. The first is a coefficient that gives the exponential law according to which the current varies during its propagation; the second is analogous to the impedance, and governs the phenomena which occur at the junction of two differently constituted lines. These two factors may be calculated from the line constants, though the lines are never homogeneous, and in consequence the theoretical formulæ are not rigorously applicable. It is, therefore, absolutely necessary to find some means of direct measurement. M. Devaux-Charbonnel, in a recent issue of "La Lumière Electrique" shows that this operation can be easily accomplished, whatever the length of the line under test, if the line be connected through an impedance exactly equal to its characteristic. In this case no reflection phenomena arise. Measuring the impedance at the sending end at once gives the characteristic, and the ratio of the sent to the received current gives the attenuation in the form of a simple exponential. This method, the author considers, should be of great use owing to the ease and precision with which it enables measurements hitherto considered difficult and inaccurate to be made.

Verband Deutscher Elektrotechniker.—The annual general meeting of this Institution began on Monday, May 29th, the meeting place this year being Munich. According to the "Elektrotechnischer Anzeiger," the president, Prof. E. Budde, after replying to the speeches of welcome made by Oberbürgermeister von Borscht, of Munich, and Prof. Schröter, delivered an address in which he referred to the development of electrotechnical work during the last twelve months. Fresh capital had been invested and the amalgamation of large firms had made further progress. The proposed tax on electricity was likely to bring in about £400,000. Heavy current work had made steady progress, while the erection of "overland" stations was being continued. The necessity for such stations would become more and more pressing as the use of the electrical plough developed. As regards transmission, pressures of 110,000 volts were already in use and even higher voltages were being considered. Street railways would celebrate their jubilee during the present year, and it was already 30 years ago since Werner Siemens had set the first electric railway to work. The use of underground railways in large towns, thus avoiding congestion in the streets, was becoming more and more extended, and the employment of electric traction for

Digitized by Google

main-line working was also making steady headway. In conclusion, the president referred briefly to telegraphy and telephony, and mentioned the work of the International Electrotechnical Commission.

International Congress at Turin.—Further particulars in connection with the International Congress of the Applications of Electricity to be held at Turin in September have come to hand and include a list of the Papers so far arranged and the official subjects for discussion with the names of the respective reporters. In view of the support that has already been received, the Organising Committee feel sure that the Congress will prove of considerable importance to the electrical world. The final programme is to be sent to all members of the Congress who apply to the Executive Committee for it. Applications for membership and any request for information should be sent to the secretaries at the following address: Congresso di Elettricità, Politecnico, Torino, Italy.

Engineering Standards' Committee.—The Engineering Standards' Committee have just issued a copy of the "Report on British Standard Threads, Nuts and Bolt Heads for Automobile Construction" (No. 54). The sub-committee which was entrusted with the drafting of this report was a very representative one, its membership comprising delegates from the leading technical institutions and societies associated with the automobile industry. To supply the great want of interchangeability in the smaller component parts of automobiles the Committee have decided to recommend the use of the British Standard Fine (B.S.F.) Threads, but they have found it desirable to alter the pitch of the ¼ in. size from 25 to 26 threads per inch, and to introduce a new standard size of $\frac{3}{32}$ in., with 28 threads per inch. While recommending these threads for general use the Committee anticipate that there will be cases in which a special thread may be required, and here they have recommended the adoption of the Whitworth form with a uniform pitch of 16 threads per inch irrespective of the diameter. With regard to the standard nuts and bolt heads the British standard widths across the flats have been adhered to, but in order to save weight and space they are applied to a larger size of bolt. The report is published by Messrs. Crosby, Lockwood & Son, and is obtainable either from them or at the offices of the Committee at a price of 2s. 6d. net.

Hydro-Electric Power in the French Alps.—According to a statement recently made in "L'Industrie Electrique," the total capacity of the hydro-electric stations at present working in the region bounded by the Alps, the Rhone and the Mediterranean is 475,000 H.P. This region covers rather over 2,000 sq. miles and 10 departments, namely: Basses-Alpes, Hautes-Alpes, Alpes-Maritimes, Bouches du Rhône, the Sère, Savoie, Haute-Savoie, Var and Varcluse. The power is at present used in the following ways: Metallurgy 200,000 H.P., power and light 32,000 H.P., chemical products 60,000 H.P., paper and wood works 25,000 H.P., traction 10,000 H.P., and various 8,000 H.P. The minimum power at low water is at least 180,000 H.P., while the capacity of stations under construction is 80,000 H.P. and of proposed stations 600,000 H.P. The following table gives details of the various stations:—

Watersheds.	Horse-power. Minimum.	Total installed.
Dranse	600	1,100
Arol	14,000	54,880
Fier	4,000	14,760
Rhône (Jonage)	12,000	22,000
Isère	105,000	26,000
Drôme	570	670
Lez	—	90
Durance	30,500	93,000
Argens	750	3,800
Siagne	3,500	8,600
Loup	2,000	3,200
Var	4,800	8,350
Roya	150	275
Total (in round figures)	180,000	475,000

National Physical Laboratory—Collected Researches. Vol. VII.—This volume, which has recently come to hand, contains an account of numerous researches which have been carried out by members of the staff of the National Physical Laboratory. They appeared in various publications during 1910, and are as follows:—

"Some Phenomena of Magnetic Disturbances at Kew," by Dr. C. Chree, F.R.S. ("Philosophical Transactions of the Royal Society," series A, Vol. CCX, 1910); abstract in THE ELECTRICIAN, Vol. LXV., p. 607. "Discussion of Results obtained at Kew Observatory with an Elster and Geitel Electrical Dissipation Apparatus from 1907 to 1909," by Dr. C. Chree, F.R.S. ("Philosophical Magazine," September, 1910) "On the Properties of some Alloys of Copper, Aluminium and Manganese (with an Appendix on the Corrosion of Alloys of Copper and Aluminium when exposed to the Sea), being the Ninth Report to the Alloys Research Committee of the Institution of Mechanical Engineers," by Dr. W. Rosenhain and Mr. F. C. A. H. Lantsberry ("Proceedings" of the Institution of Mechanical Engineers. 1910). "Report on the Progress of the National Experimental Tank," by Dr. R. T. Glazebrook C.B., F.R.S. (The "Transactions" of the Institution of Naval Architects, Vol. LII., 1910). "On the Use of Mutual Inductometers," by Mr. A. Campbell ("Proceedings" of the Physical Society of London Vol. XXII.; also "Phil. Mag.," April, 1910; abstract in THE ELECTRICIAN, Vol. LXIV., p. 728). "Comparative Life Tests on Glow Lamps," by Messrs. C. C. Paterson and E. H. Rayner (THE ELECTRICIAN Vol. LXV., p. 983. September 9, 1910). "On a Method of Counting the Rulings of a Diffraction Grating," by Dr. G. W. C. Kaye ("Philosophical Magazine," October, 1910). "The Expansion and Thermal Hysteresis of Fused Silica," by Dr. G. W. C. Kaye ("Philosophical Magazine, October, 1910).

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Dr. R. Beattie concludes his article on "Harmonic Analysis Diagrams."

Mr. C. C. Hawkins concludes his article on "The Principle of the Static Balancer."

At a recent meeting of the National Association of British and Irish Millers, Messrs. W. Cramp and B. E. Stott read a Paper on "Flour Mill Power Schemes."

In a Paper read before the American Institute of Electrical Engineers on "Electrification Analysed and its Practical Application to Trunk Line Roads, inclusive of Freight and Passenger Operation," Mr. W. S. Murray describes the results of single-phase traction on the New Haven Railroad. The subject of electrification of trunk lines is discussed in our Leading Article.

Mr. J. Miller recently read a Paper before the Rugby Engineering Society on "Electric Power in Collieries."

A letter of some interest, from the pen of Mr. C. Pfeffer, general manager of the A.E.G. Electric Co., on the subject of German tariffs on electrical machinery and materials, appears on another page.

The rail-less trolley sections of the Leeds and Bradford tramways will be opened on Tuesday next.

Particulars are given of the R.A.C. Report on the recent trials of the "Thomas" electromechanical transmission.

A special Committee of Holborn Council have recommended the acceptance of the joint tender of the Gas Light & Coke Co. and the Metropolitan Electric Supply Co. for lighting the streets of the borough for 10 years for £7,645 per annum.

Municipal Loans.—An inquiry was held on Wednesday into the application of Stoke-on-Trent Corporation for permission to borrow £60,000 for the erection of new three-phase plant.

An inquiry was held at Manchester on Tuesday into the application of the Corporation to borrow £12,186 for additional generating plant and to divert £50,000 from a previously authorised loan for street lighting to extension of mains and services.

Walsall Council have received sanction to a loan of £14,510, and Wimbledon and Newcastle (Staffs.) Councils have applied for permission to borrow £5,970 and £54,000 respectively, for their electricity departments.

In forwarding sanction to a loan for extensions of the electricity undertaking, the Board of Trade point out the necessity for providing an adequate reserve or depreciation fund to meet renewals of plant, &c.

Parliamentary.—Further consideration of the Coal Mines Bill in a Standing Committee of the House of Commons was resumed on Wednesday, when clause 32 was added.

The Corporation of London (Bridges) Bill was re-committed on Wednesday.

A Select Committee of the House of Commons has resumed consideration of the Greater London Railway Bill.

Legal.—On Wednesday the Court of Appeal commenced hearing the cross appeals in the case of the National Telephone Co. v. the Postmaster-General in regard to the sufficiency of the notices given by the Postmaster-General rejecting certain portions of the Company's plant, &c.

Digitized by Google

The action brought by Hartlepool Electric Tramways (Ltd.) against the Corporation of West Hartlepool in regard to the purchase by the Corporation of two of the Company's tramway routes was again before Mr. Justice Bray on Wednesday, and, after further argument, his lordship reserved judgment.

Companies' Meetings.—At the first meeting of the shareholders of the Peel-Conner Telephone Co. the chairman (Mr. Hugo Hirst) had an agreeable story to tell of the Company's progress. Mr. Hirst claimed that the outlook for the Company is excellent.

The report of the Aron Electricity Meter (Ltd.) gives particulars of the progress made during the past year. Extensions of the factories have been made in order to cope with the increased business.

The report of the Westinghouse Electric & Mfg. Co. gives particulars of the work undertaken by the Company and its subsidiaries during the year ended March 31.

OBITUARY.

J. J. Marr.—We regret to record the death of Mr. J. J. Marr, electrical engineer, which took place at Seacombe on the 11th inst. Mr. Marr, who was in his 72nd year, was born in Edinburgh. In 1868 he moved to Liverpool and entered the service of Messrs. Chadwick, ships' telegraph engineers, Bootle, subsequently joining the staff of Messrs. Edison & Swan. In 1874 he started on his own account in Moorfields, Liverpool, where he continued until his death.

PERSONAL NOTE.

We understand that Prof. D. S. Capper, though still confined to his bed, is making satisfactory progress.

APPOINTMENTS VACANT AND FILLED.

Hammersmith (London) Borough Council invite applications for the appointment of a fourth assistant engineer at the electricity works to act as junior engineer-in-charge. Salary £130, rising by annual increments of £5 to £150. Forms of application, &c., from the engineer and manager (Mr. G. G. Bell), 85, Fulham Palace-road, W., to whom applications by 10 a.m. Friday, June 30. See an advertisement.

A junior assistant electrical engineer is required by a firm of consulting engineers in Westminster. See an advertisement.

A capable engineer, with knowledge of meters and instruments, is wanted for indoor commercial work. See advertisement.

Teachers of experimental physics and chemistry are required for Government Schools, Cairo and Alexandria. Salary £369. Two years' engagement. For further particulars apply (by June 20) to Mr. J. W. Crowfoot, care of Director of Egyptian Educational Mission, 36, Victoria-street, London, S.W.

A demonstrator in electrotechnology (£100 a year) and a visiting teacher of telegraphy and telephony (one evening per week, 10s. 6d.) are required at L.C.C. Paddington Technical Institute. Application form (T. 17) can be obtained from the Education Officer, Victoria Embankment, W.C. Applications by 11 a.m. June 26.

A demonstrator in physics is required for Armstrong College, Newcastle-on-Tyne. Salary £100, rising to £120. Applications to Mr. F. H. Pruen, secretary, by June 23.

London County Council require a teacher of practical electric wiring. Form of application (T. 17) from the Education Offices. Applications by 11 a.m. June 19.

In connection with the organisation of the new department of heating and ventilating engineering at University College, London, towards which London County Council have made a grant in aid, Mr. Arthur H. Barker, B.A., B.Sc., vice-president of the Institution of Heating and Ventilating Engineers, has been appointed lecturer for the session 1911-12. Mr. E. Kilburn Scott has been appointed lecturer in electrical design for the session, in succession to Mr. H. M. Hobart resigned.

Mr. W. W. Mayne of Rutherford College, Newcastle-on-Tyne, has been appointed director of the technical schools of the Cheltenham Local Higher Education Committee at a salary of £220, rising to £250.

Mr. Stephen H. Piper, B.Sc., has been appointed assistant lecturer and demonstrator in physics at University College, Nottingham.

Mr. H. W. Turner, of the Imperial College of Science and Technology, has been appointed chief assistant lecturer in the engineering department of the Borough Polytechnic Institute.

INSTITUTIONS AND SOCIETIES.

Electrical Contractors' Association.—The annual dinner of this Association will be held on Monday, July 3rd, at Frascati's Restaurant, under the chairmanship of Mr. Geo. Harland Bowden.

Physical Society.—The meeting of this Society, previously announced to be held on Friday, June 23rd, has been postponed to Friday, June 30th, at 5 p.m., the meeting place being the Imperial College of Science.

Royal Society.—At the conversazione held on Wednesday the exhibits, generally speaking, were not of particular physical interest, or at least they were not particularly novel, as they were mostly shown at the conversazione held last month. One of the most interesting exhibits was that by Prof. S. P. Thompson, F.R.S., and Prof. E. G. Coker, and consisted of experiments with polarised light showing transparent objects in a state of strain. This method is particularly valuable as a means of showing students easily how the stresses are distributed when the object is put into a state of strain, and it is found that quantitative results can also be obtained. This exhibit also included a remarkably fine quarter wave plate of mica cut from clear sheets of mica supplied by Messrs. Wiggins, the diameter of the plate being 19 in. Sir James Dewar, F.R.S., showed how the motion of a radiometer is stopped by a very high vacuum, charcoal cooled in liquid air being used for the purpose. The limiting pressure is about one fifty-millionth of an atmosphere. Messrs. Elliott Bros. showed experiments illustrating the application of the gyrostat to the mariners' compass, and Dr. Deane Butcher showed interesting examples of osmetic growth as on the last occasion.

University of London.—At a meeting of the Senate on Wednesday last Sir Wm. Collins was elected Vice-Chancellor of the University for the year 1911-12 in succession to Prof. M. J. M. Hill, F.R.S.

Institution of Gas Engineers.—In connection with the annual conference of this institution, which was held at Glasgow this week, an exceedingly pleasing incident at the luncheon in the City Chambers, over which the Lord Provost, the Hon. A. McInnes Shaw, presided, was the presentation of a beautifully designed and mounted president's hammer and striking board sent by the German Association of Gas and Water Engineers with a letter, expressing the feeling of friendly relationship existing not only between the members of the two societies but also between the citizens of the two nations. The gift was received with great appreciation and was suitably acknowledged.

Royal Meteorological Society.—At a meeting of this society held on Wednesday June 14th, Dr. C. Chree, F.R.S., read a Paper giving the results of a discussion of the barograph records kept by the late Mr. R. Bell at Castle O'er, Dumfriesshire, during the seven years 1902 to 1908. These results show a well-marked principal maximum and minimum at 10 p.m. and 5 a.m. respectively. Every single year agrees in this except 1908, which puts the maximum at 7 a.m. The existence of a secondary maximum and minimum is unmistakable, but while the hour of occurrence of the former is clearly 11 a.m. that of the latter is less distinct. It seems to be 4 p.m., but a longer series of observations would have been necessary to confirm this. Mr. Spencer C. Russell gave an account of a number of interesting experiments which he had carried out at Epsom during the last two years in order to obtain a permanent record of the variations in the size of raindrops as and when they occurred. The most satisfactory results were obtained by using plaster of paris; slate covered with oil caused the drops to be broken when the rain was very heavy and was therefore not very suitable. A joint Paper by Dr. W. Makower and Messrs. A. J. Makower, W. M. Gregory and H. Robinson was read describing the experiments which they carried out last August at Ditcham Park, near Petersfield, in Hampshire, to investigate the electrical state of the air at different heights above the ground.

ARRANGEMENTS FOR THE WEEK.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued for the coming week:—

Monday, 19th, "A" Company.—No parades.

Tuesday, 20th, "B" Company.—No parades.

Wednesday, 21st.—Detachments for the "Coronation and Royal Progress" will parade at headquarters for ceremonial drill at 7 p.m. Dress, blue clothing, drill order, with water-bottle and haversack. Special orders will be sent to each concerned.

Thursday, 22nd, "C" Company.—No parades.

Friday, 23rd, "D" Company.—No parades.

Saturday, 24th—No parades.

NOTE.—Headquarters will be closed during Coronation Week for all purposes except Coronation duty.

ELECTRIFICATION ANALYSED, AND ITS PRACTICAL APPLICATION TO TRUNK LINE ROADS, INCLUSIVE OF FREIGHT AND PASSENGER OPERATION.*

BY W. S. MURRAY.

Summary.—The author advocates the standardisation of 11,000 volts, 25 cycles single-phase for all trunk lines. A description is given in detail of the operation of the New Haven equipment, and data as to delays, performance of locomotives, &c. The development of the present equipment and full particulars of the work now under construction are also included in the Paper.

Succinctly, the object of this Paper is to place before the practical engineer and railroad man the facts concerning trunk line electrification, and bring home to him the simple truth that it can be treated in a class of its own. I venture the opinion that there is no trunk line situation that exists to-day, but what there is a construction drawing in the New Haven engineering files that would have immediate application. The religion of the Paper is to preach the doctrine of universal use of single-phase current on trunk-line roads, inclusive of suburban and terminal territory, as applied to freight and passenger operation, and I offer for consideration the standardisation of 11,000 volts on the contact wire and a system frequency of 25 cycles. In recommending 25 cycles, the author has in mind that the future will undoubtedly see single-phase locomotive induction motors and probably single-phase current received at the terminals of the locomotive and transformed into direct current without the use of any rotating element within the locomotive.

In the generosity of his heart, the practical railroad man has looked with some commiseration, some kindness, and lately with some real interest upon those electrical engineers who are truly endeavouring, while engrossed in the principles of their own electrical art, not to forget in their studies to take into consideration the principles now of such long standing that have placed the art of steam railroading on its present sound basis. With that in mind there follows in this Paper a series of studies of a steam locomotive as it appears in its four classes on a typical trunk-line property. The whole problem of electrification, if viewed from the point of whether it is to pay, settles down to how much it costs to produce the necessary tractive effort required in (1) The passenger express locomotive; (2) the passenger local locomotive; (3) the freight road engine; (4) the freight switch engine; together with such other costs incident to the electrical system.

Steam Passenger Locomotive.—In a discussion of a Paper by Messrs. Stillwell and Putnam†, the writer presented a tabulated set of figures with reference to the fuel required for the operation of steam passenger and freight locomotives, and the yearly cost of their maintenance and repairs. He was obliged to omit, however, the actual data from which the results were obtained. A very fair express and local trunk-line service is offered in the trains of these respective classes between New Haven and New York City; and, as explained in the discussion previously referred to, a month was devoted to the study of the capacity of engines required and the coal consumed in such services over the 61·5 miles of route between New Haven and Woodlawn. In the present Paper are set out the information with reference to average cut-off, boiler pressure, water consumption, indicated horse-power and grade—all referred to stations along the route.

The averages of five tests over the route are as follows:—

Express runs.	Train 63.	Train 16.
Average weight of train with engine	328 tons	414½ tons
Time	73 min. 17 sec.	75 min. 5 sec.
Average I.H.P.	833	845·6
Average I.H.P. per ton	2·54	2·04
Water consumption per ton-mile	1·367 lb.	1·194 lb.
Local runs.		Train 284
Average weight of train with engine		294·3 tons
Time		127¼ min.
Average I.H.P.		626·8
Average I.H.P. per ton		2·13
Water consumption per ton-mile		2·034 lb.

The analysis of the steam engine under operation for trunk-line conditions incident to the New Haven road caused us to choose for our passenger unit a locomotive the normal capacity of which was 1,000 H.P. at the rim of the locomotive wheels, and this size in practice has borne out our estimate of the capacity required

Steam Freight Locomotive.—A series of tests was carried out, the runs being over a distance of 55½ miles, and in this case trains in the regular log of the New Haven operation varying in weights between 720 and 1,500 tons, including weight of engine, were used. The average of 10 tests showed the evaporation of water per pound of coal to be 6·9 lb., also the average indicated horse-power varied from a minimum of 655 to a maximum of 892, the average speed varying from 23·5 miles per hour minimum to 31·5 miles per hour maximum.

The electric locomotive we have designed to handle our general class of freight service has a normal horse-power rating of approximately 1,400 H.P. This capacity provides a margin above the requirements indicated in the tests, but is highly desirable in virtue of its affording the electriclocomotive an opportunity to operate heavier trains and at a higher schedule speed than the steam locomotive it replaces.

Fig. 1 shows the motor characteristics of our electric road freight engine "071." Not uninteresting is the flexibility offered by the electric over a steam locomotive, in noting that its limit ation of service is not absolutely confined to one class. When the same locomotive (071) made a local schedule in passenger service, handling a total weight of 500 tons, the watt-hours per ton-mile were under 60.

Steam Locomotive Switcher.—By far the most interesting investigation of the four types of steam engines employed in trunk-line service was that of the steam-switching locomotive. In the many yards of the New Haven lines none afforded a better opportunity to study this type of engine than at Harlem River, where the duty imposed upon the switching locomotive, beside that of classification, included also float work, calling into account the necessity of heavy drafts of power and sustained for periods longer than usual to other

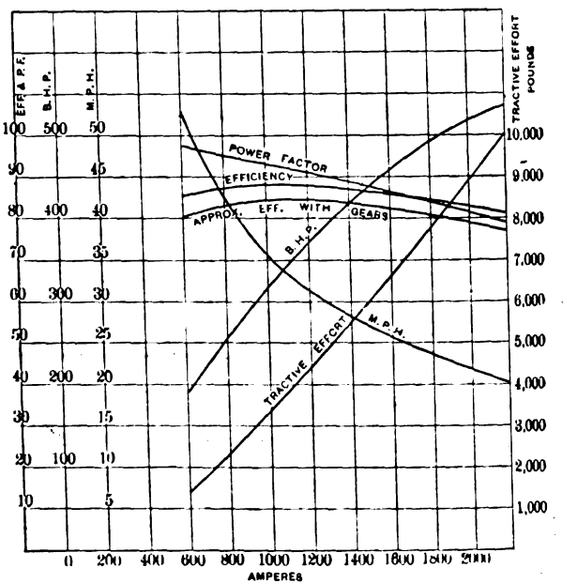

FIG. 1.—SPEED-TORQUE CHARACTERISTICS OF 25-CYCLE RAILWAY MOTOR

switching yards; but even with this additional duty to perform, th relatively small amount of energy required for this work yielded great surprise. Careful observations for 12 days of switching move ments were made on switch engine 2,392, and showed the following averages:

Total time of throttle open	.....	36·7 per cent.
Total time engine in motion	.....	62·65 per cent.
Total time engine standing	.....	37·5 per cent.
Rate of water used per hour	.....	12,633 lb.
Total water used—7·5 hours	.....	37,603 lb.

Assuming 40 lb. of water evaporated per horse-power hour, whic is probably much lower than the actual, it is seen that the averag horse-power during the time the throttle is open is approximatel 313 H.P.; but it is noted that the engine is developing power for onl 36·7 per cent. of the time, and thus the average energy develope during the hour is approximately 115 H.P.

The reduction of the energy developed by a switching engine to a average of 115 H.P. has been something of a revelation to the write and the two most important things it suggests are: (1) That i switching, yard speeds can be greatly increased by the use of an ele tric switcher of very much less engine capacity than that used in th steam switcher. (2) On account of the low average rate of energ required for their operation, a central power station will deliver at f higher efficiency the power necessary to the electric switching engin than that obtained from the power plant individual to the stea switching engine itself.

Immediate application of this statement is seen in the ratio of th pounds of coal burned to the number of horse-power hours develope which averaged 6·4. Increasing this by the coal burned during th idle hours of the engine, this ratio approximates 8. It has be demonstrated that the ratio between the coal burned for operati

* Abstract of a Paper read before the American Institute of Electrical Engineers.

† THE ELECTRICIAN, Vol. LVIII., p. 758.

Digitized by Google

passenger trains by electric rather than steam locomotives is one to two. In the case of switching engines this rate is much greater; a figure of one to three being conservative.

Record of Single-phase Trunk Line Operation.—In the Paper entitled "The Log of the New Haven Electrification,"* there was given a table of train minute delays with their causes. Similar data covering a consecutive period of six months—one year later—are given in the present Paper. The most interesting point is the disappearance of delays, with the exception of one amounting to over 300 train minutes. The total delays for the six months' consecutive operation in 1908 were 10,373 train minutes; and for the six months' consecutive operation in 1909 the train minute delays were 2,076, or one-fifth of those for 1908.

A diagram in the Paper shows that whilst the electric locomotive failures were nine per 100,000 electric engine miles, the steam locomotive average for all the divisions of the New Haven was 21. Thus, the electric locomotive service is 133 per cent. better than the steam.

Power House.—Our experience with three-phase generators indicates that their choice, as against single-phase, is the proper one. The three-phase star winding offers at all times a spare leg in any of the generators in the event of any trouble with the two other legs, and at the same time permits simultaneous supply of current from the same generating system for the operation of either three-phase or single-phase apparatus. In the case of the Cos Cob station, this is instanced in the fact that we are supplying three-phase current for our Greenwich lighting plant and are now arranging for the supply of power for the operation of sub-stations at White Plains, Mamaroneck, Porchester, Stamford, South Norwalk and Bridgeport; in which sub-stations there will be operated motor-generator or synchronous converter outfits for the supply of direct current for railway purposes at the above-mentioned places. By the installation of copper-clad rotating fields in our generators, the unbalanced voltage between phases is reduced to a minimum, and such as remains is easily compensated for by arrangement of transformer taps in the sub-stations reducing the three-phase current from high to low voltage for motor or synchronous converter application.

Distribution System.—This is a unit system comprehending the main line of the New York, New Haven and Hartford road between Stamford and Woodlawn, the six-track Harlem River freight and passenger connection from New Rochelle to the Harlem River terminal, New York City and the New York, Westchester and Boston line running from the West Farms connection to the Harlem River branch up to White Plains, New York. Throughout this extensive area, embracing in all over 300 miles of single track, there is not a single sub-station, and no electrical pressure higher than 11,000 volts is used. Also, all of the copper installed over the tracks, just above the steel contact wire, is in the same phase, unaugmented by any feeders other than the by-pass wires installed on the lower cross-arms of the catenary posts to permit sectionalisation of anchor bridges.

Of interest, also, is the very successful control system common to all the sectionalising breakers throughout this triple arrangement of distribution, the function of which is to ensure a reliable selective action of circuit breakers to confine any line trouble to its specific locality. Briefly described, the control consists of a single wire, upon which is impressed the normal voltage of the system when a short-circuit occurs anywhere, but not until the automatic resistance at the power station has been cut in series with the line; at which moment the control wire by means of transformers passes current through the tripping coils of the sectionalising breakers, and the two breakers that are directly feeding the short circuit are immediately opened. The resistance, thus inserted, however, has reduced the short-circuiting current to a minimum and relieved greatly the duty of opening the breakers. This resistance scheme has proved itself to be a most valuable acquisition to the system, serving at once to lessen the duty on both generating and distributing apparatus.

The maximum pressure drop on the system during the 5:30 p.m. suburban load peak is such that the voltage at Harlem River station, which is 25·6 miles from Cos Cob, is 9,151 volts—entirely sufficient to maintain all passenger and freight trains on schedule.

Storage batteries for trunk line electrifications are not economical. This is true whether the propulsion current be direct or alternating. The efficiency of electric energy production is higher with than without the battery, on account of the greater constancy of load for the former conditions, but the difference is so small that it is, at least for trunk line conditions, offset by the increase of output required and the cost of maintenance of the battery. In this connection should be noted the great importance of the added freight and switching loads in improving the station load factor, due both to the exclusion of freight trains from main tracks during the hours of passenger peaks and to the latitude of operation afforded in fixing freight schedules; thus discharging the functions of a battery while escaping the penalties of battery losses and maintenance charges.

* THE ELECTRICIAN, Vol. LXII., p. 493.

Insulation.—There are points in the overhead system where the factor of insulation should be higher than at others. In the order of their higher degree of insulation requirements, I would mention: (1) Sectionalising switches; (2) Sectionalising 'bus bars; (3) Dead-end catenary insulators; (4) Intermediate catenary insulators.

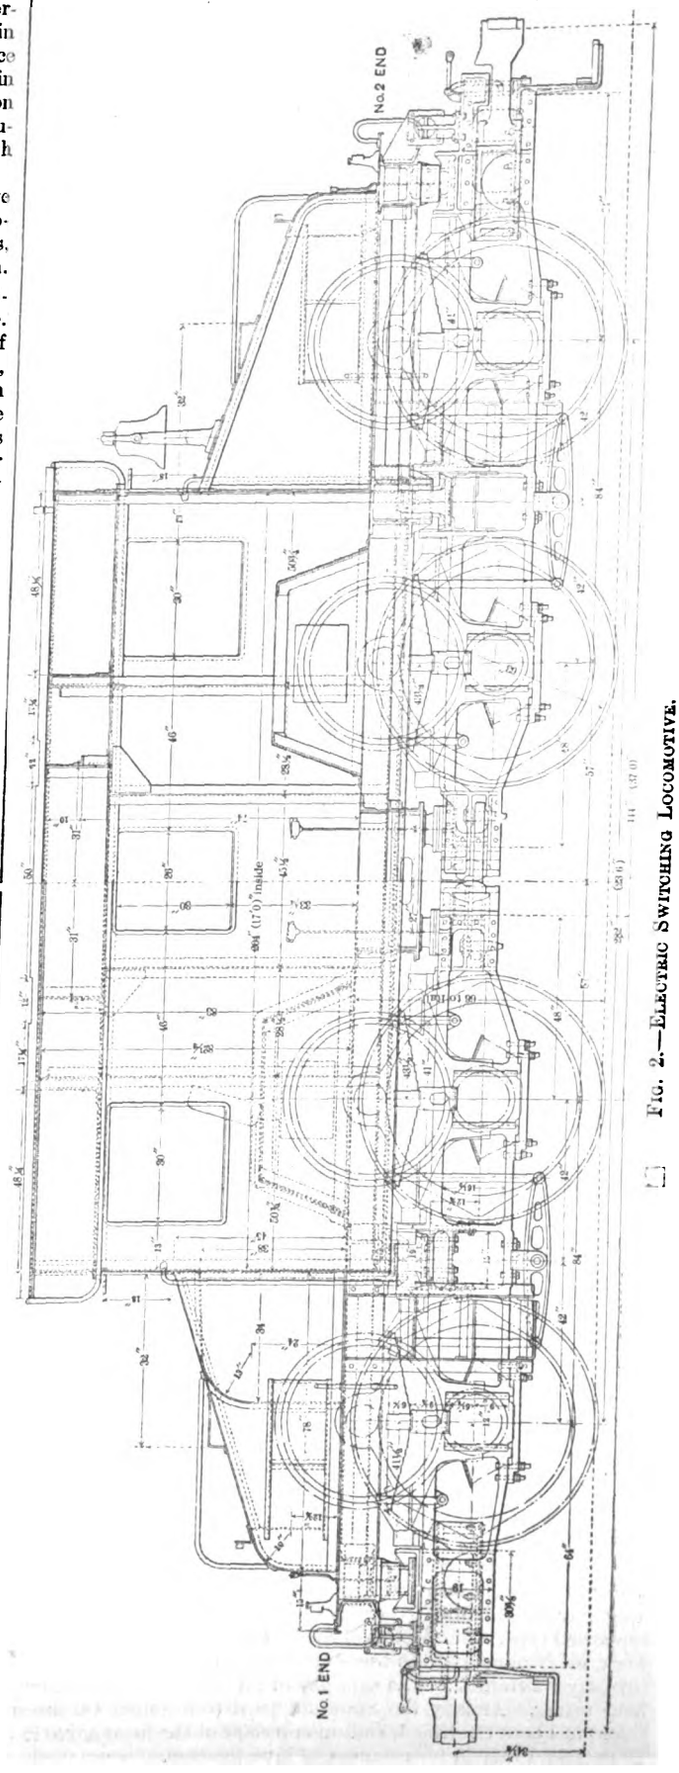

FIG. 2.—ELECTRIC SWITCHING LOCOMOTIVE.

When the New Haven electrification was completed in 1908, the best dead-end insulator then on the market was one rated at 7,000 lb. mehcanically and 40,000 volts electrically, and cost $27. We found

Digitized by Google

in a very short time that two of these had to be used in series, which with the yoke harness made the cost $61. To-day we have placed orders for dead-end (or strain) insulators, every one of which is tested before shipment, for 110,000 volts under a mechanical strain of 35,000 lb., and they have an ultimate mechanical tensile strength of 50,000 lb. The cost is now $7 as against $61.

Steel Contact Wire.—It is difficult to place sufficient emphasis on the importance and value of the steel contact wire which was put in service on the New Haven lines in 1908. Micrometer measurements of the steel wire taken at a point of maximum wear directly in front of one of our low highway bridges where the steel wire is on a gradient of 2 per cent. show that the actual vertical wear of the wire since its first installation 30 months ago is 0·028 in., *i.e.*, practically 4·5 per cent. per year of the half diameter of the wire (one-half taken to permit wire to be held in clips). Even on this vertical diameter basis, it indicates a life of over 20 years; but as a matter of fact the life will be much more, for the reason that as the vertical diameter lessens the breadth of contact increases throughout, thus diminishing the rate of vertical wear. Of further interest, too, is the fact that there is practically no corrosion on the wire; for, like the traffic rails in service (only much more so) the wire is constantly covered by a film of grease– due to a generous amount of this material being placed on the pantagraph shoe.

It was thought, due to the coefficient of expansion of steel being less than that of copper, that the extreme variations in temperature might cause the contact wire to break; but this feature has not manifested itself. Our experience with this steel wire justifies its presence and it will be used throughout our catenary construction over the New York, New Haven and Hartford, Harlem River branch and the New York, Westchester and Boston electrification; thus serving something over 300 miles of single track.

Electric Locomotives.—In a previous Paper* there was given a list of mechanical and electrical changes that were being made in the passenger type of locomotive. The introduction of a completely cushioned locomotive (with the exception of the wheels and axis) on heavy trunk line rails was of keen interest to the maintenance-of-way department, and a careful study of its effect is being made. They have already reported a decided improvement of rail life and alignment.

The initial installation of the New Haven road provided for locomotive propulsion of all trains. During the past two years close attention has been given to the development of three other classes of equipment, namely: the multiple-unit train, the road freight engine and the switching engine. The future will see the gradual replacement of the locomotives by multiple-unit cars for suburban service, and the continued use of the locomotives thus replaced in the express service.

The electrical characteristics of the freight locomotive have been referred to in connection with Fig. 1. One of the impressive characteristics of this engine is its ability to start very heavy trailing loads, *e.g.*, 2,160 tons. This, the largest load we were able to assemble, was easily accelerated. The locomotive is of the quill-geared type, entirely spring supported (except wheels and axle), with pony wheels leading and trailing; and four propulsion motors are provided, each with a normal hourly rating of 396 H.P.

This type of locomotive is of higher power and differs from our present passenger engine in the arrangement of its apparatus, it being fitted with a central truck over super-imposed motors, with the control apparatus arranged in the middle of the cab and a full passage on each side, giving excellent light for inspection of the various items of equipment. This is a marked improvement over the previous type of locomotive, the apparatus and control of which is arranged on the sides of the locomotive with a central aisle.

Besides the above-described type of electric road engine, there is being built for the New Haven road two other types of equivalent hauling capacity; one of the side-rod design with four-motor equipment, the other having its power divided between eight motors. All these locomotives have been designed to operate both on alternating and direct current. In every instance this condition has increased weight and complicated control.

Fig. 2 gives an outline elevation drawing of our switching locomotive. This engine is coming to us as this paper goes to press. To the writer, it is the most interesting of all, though small and apparently insignificant. Like its larger brothers, it too is of the quill spring-supported type. On account of the buffing strains incidental to yard work, its framing and the assemblement of equipment is made particularly substantial. The capacity of its motors is 600 H.P. on the hour rating. Already the Stamford yard (containing 4·2 miles of track) has been electrified, and upon receipt of the locomotive it will be exercised therein for commercial investigation.

In connection with our alternating-current multiple-unit train development, we have had in operation a multiple-unit equipment consisting of four motor cars and six trailers. Again the requirement of direct-current operation has super-imposed upon this equipment the handicap of extra weight and complication of control. In spite of great strides in the simplification of the alternating-current-direct-current apparatus, the weight of the equipment is 55,405 lb., as against 47,250 lb. for a straight single-phase equipment.

Catenary Construction.—A number of drawings showing the work are reproduced in the Paper, and include the Hoosac Tunnel catenary construction. While the electrification of the tunnel and its approaches is not yet complete, it is rapidly nearing this stage.

The Hoosac Tunnel electrification is characteristic for its simplicity. In the case of its power house, two turbo-generators each of 3,000 kw. capacity are installed. Fig. 3 shows the arrangement of the supports in the tunnel. Four insulators, each capable of resisting 150,000 volts to earth, are installed on the bracket, two for each track. They are arranged in series, so as to give a combined strength of 300,000 volts. The outside insulator holds the track messenger, to which is pendent the contact wires below. Some criticism might be offered in using a 150,000-volt insulator, where 40,000 might have sufficed, but it has been forcibly impressed upon the writer that it is *good* engineering to spend money on insulation. All of the insulators purchased for the Hoosac Tunnel electrification, inclusive of the tunnel itself and its outside approaches, did not total one-half of one per cent. of the total expenditure.

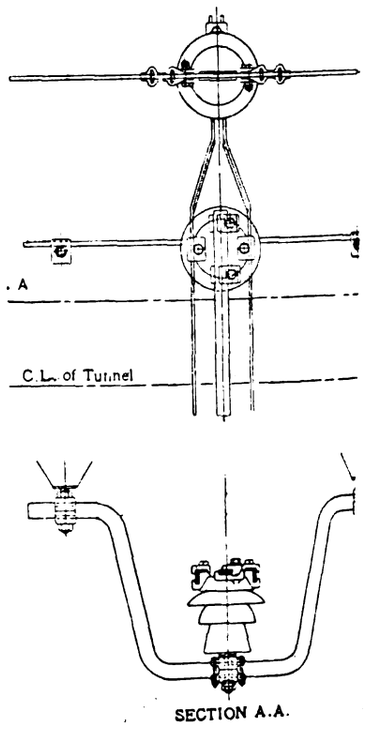

FIG. 3.—HOOSAC TUNNEL CATENARY BRACKET.

Electrification Costs.—Not until the electrical system of the New Haven road is a unit in itself rather than a mixed service of steam and electricity can its true economies of electrical traction be discussed. Suffice it to say that the two great departments of economy be in the saving of fuel and repairs to rolling equipment.

In writing this Paper I have endeavoured to avoid a discrimination between systems; I wish, however, to state very plainly that I am not at all in sympathy with the attitude on the part of some who claim some recognition in the field of railroad engineering when they suggest the advisability of not advocating any particular system of electrification. To discuss electricity v. steam without a recommendation of system in the specific cases of trunk line work, in my judgment, is to launch a ship upon a rough and windy sea without a rudder. My experience with the single-phase system v. other competitive systems, affords me the sincere conviction that, under practically all conditions of trunk line consideration where the traffic is of the same amount and character, or indeed much less than that which is comprehended in the mileage that this Paper covers, its first cost is, at the greatest, not more than 85 per cent. of its next best competitor, and its operating costs less than the above percentage.

The above statements should not be taken to mean that all trunk line railroads considering electrification can electrify and save money; indeed, its general application is prohibitive.

In conclusion, this Paper is not an argument for the single-phase system. Statistical records of the first cost and operating expense make such a course unnecessary. It has been written with the purpose of placing in the hands of those interested in the electrification of railroads the facts concerning the application of single-phase current to nearly 500 miles of trunk line property and to make a specific recommendation that for the sake of simplicity and economy it be the adopted system for other trunk line properties which the future will see electrified.

The Paper with its appendix contains 76 illustrations, including drawings of the overhead catenary construction for the New York, New Haven and Hartford Harlem River branch; the New York, Westchester and Boston Railroad; and the Hoosac Tunnel electrification.

* THE ELECTRICIAN, Vol. LXII., p. 493.

ELECTRIC POWER IN COLLIERIES.*

BY JAS. MILLER.

On deciding to utilise electrical energy in a colliery, the engineer has to determine whether it is more economical to instal his own generating plant, or to take a supply of energy from a local power company when available. This obviously depends to a great extent on local conditions, but it is probable that in most cases it is more profitable to instal generating plant at the colliery. To begin with, coal is much cheaper at a colliery than elsewhere, and at those collieries where the coal is not used for coking purposes, and therefore generally washed, there is usually an overabundant supply of washings or smudge for which there is practically no market, and which provides a sufficiently good fuel for steam raising. These coal washings if not used at the colliery have to be stored away somewhere, and usually rent paid for the ground. This means a great saving in the coal bill of a colliery power station over that of a power company, who for the purposes of efficient steam raising have to burn coal of much better quality.

A great deal depends on the nature of the work for which the power is to be used. If the load is to consist mainly of pumping, coal-cutting and ventilation, then the load factor on the plant will probably be very high, and so the generating plant can be run very economically, but if the load consists mainly of haulage, especially of the "main" or "main and tail" type or electric winding, then the load factor may be very low indeed, possibly as low as 5 per cent., in which case the plant would necessarily be run at a very low efficiency, and thus it might possibly be cheaper to take power from some supply company when available.

The question of generating plant depends entirely upon the conditions existing at the particular colliery. Of recent years a new prime mover has become available, and is now used on a large scale at collieries. This is the exhaust steam turbine. At many collieries there is a very large quantity of exhaust steam from winding, haulage and fan engines, which, before the introduction of the exhaust steam turbine, was discharged to the atmosphere and lost. Obviously, by installing exhaust steam turbines, a great saving can be effected by utilising the energy in this steam, and it has been found that some installations of this type save their own cost after they have been running for three or four years. As the supply of exhaust steam from winding engines is intermittent, it is generally essential to instal a mixed-pressure turbine, unless there is a continuous supply of exhaust steam from some other source. Also it is necessary to instal a heat accumulator as the exhaust steam from the windings comes in rushes which, without an accumulator, would be lost through the relief valves.

The electrical side of the generating plant is, almost without exception, three-phase. The generating voltage varies between about 3,300 and 3,400, according to the requirements. Where the amount of energy to be transmitted is comparatively small and the distances not very great, it is usually found most economical to generate at about 500 volts, as the cost of transmission would be considerably less for the low voltage than for the high. Again, this saves transforming down for motors working at the coal face where high voltage cannot be used. If the amount of energy to be transmitted is large, then high-tension transmission is nearly always adopted.

With the introduction of electricity, pumping in mines has undergone a radical change. The type of pump most commonly in use for underground work is the reciprocating pump, generally of the three or four ram type. This type of pump can be made in a very compact form, and the torque on the motor is practically constant, as is also the flow of water. Again, pumps of this type can be constructed for pumping against any head. The motor generally used with this form of pump is the squirrel-cage type, as it can easily be arranged that the motor starts on light load only, a bye-pass valve being provided on the pump. This valve is opened on starting and is gradually closed as the motor speeds up. In most cases these pumps are driven direct through gearing, but in some cases belt driving is used. Another class of pump which has been used very extensively in the last few years is the turbine pump. This pump is generally placed along with the driving motor on a common base plate, and it has several distinct advantages over its rival, the reciprocating pump, viz., the space and cost are less and no heavy foundations are necessary. On the other hand where the head is very large it may be necessary to do the pumping in several stages, thus increasing the initial cost and the turbine pump is only efficient at the particular head for which it was designed.

An interesting example of the great advantage of the electrically-driven pumps over the old method of shaft pumping is to be seen at the Cowie Colliery, Stirlingshire. A steam engine was erected, operating pumps at three stages in the shaft, by means of a column of oak beams. The quantity of water pumped is 1,000 gallons per min. against a head of 340 yds. The weight of the plant is probably about 200 tons, and the initial cost, excluding boilers, was about £7,750. This plant gave great trouble, due to the breaking of pump rods and spur wheels, with a consequent great loss of time. Recently turbine pumps were installed for the same service. These pumps are arranged to pump in three stages. The bottom stage consists of a multi-stage turbo-pump direct, driven by a direct-current motor running at 1,100 revs. per min., and capable of pumping 600 gallons per min. against a head of 78 yds., and taking 80 B.H.P. The middle stage consists of a turbo-pump capable of pumping 740 gallons per min. against a head of 118 yds., when driven by a motor running at 1,000 revs. per min., and taking 86 B.H.P. The top lift pump runs at 900 revs. per min., and discharges 900 gallons per min. against a head of 144 yds., and takes 236 B.H.P. This means that the power absorbed is about 400 B.H.P., and the total cost of the plant was about £1,000, exclusive of the cost of the pipes, which were not included in the cost of the old set. When the cost of the generating plant was added to this there would still be a saving of probably £3,000, and there would be a considerable saving in the pipes as a much higher velocity would be used, hence much smaller pipes.

Another branch of pumping where the electric motor has made itself invaluable is in the driving of sinking pumps. Previously, the class of pump most commonly used was the pulsometer type. This meant running steam pipes down the shaft, with the usual trouble from leaky joints, especially as the sinking pump has to be hung in the shaft, hence a considerable amount of vibration. The pump almost invariably used where a supply of electric energy is available, is the vertical spindle turbo-type, direct coupled to a motor. This pump is hung by wire ropes from a drum on the surface, and is lowered as the shaft gets deeper, the cable for the motor being lowered at the same time. For this service a totally-enclosed motor would be almost essential, as the atmosphere is very wet.

The cutting of coal by machinery has been in operation for the last 40 years, but until a comparatively recent date it was only carried out on a very small scale. At first only direct current was used for driving coal-cutters, as it was essential for the older form of coal-cutter that the motor should be able to start up on load, that is in case the machine should be shut down on load, but at the present time there are coal-cutters which are driven by squirrel-cage induction motors, and, for the other types, induction motors with wound rotors are extensively used with great success. Current is supplied to the coal-cutter motors through flexible armoured cable wound on a drum, which is unwound to follow up the machine. A plug connector is attached to this cable which fits into a socket on the machine. This plug must be arranged with an interlocking device, so that it is impossible to remove the plug without first opening the switch, as otherwise it might be pulled out when the motor was running, thus causing a spark, and possibly an explosion if done in the presence of gas.

The motors for coal-cutters are always of the totally-enclosed flame-proof type, and the power used varies between 20 H.P. and 40 H.P. according to the size of coal-cutter used. Great care must be taken that the frame of the motor is well earthed, since there is a possibility of the motor case becoming "live," due to a breakdown in the motor, which works under very severe conditions. In some cases a protective device is installed so that the switch can only be closed if the earth connection is made, but as this device is rather complicated and delicate, it is doubtful whether it would operate well under the severe conditions existing.

There is no doubt that the judicious use of properly selected coal-cutting machinery makes possible the profitable working of the very thin seams, which could not possibly show a profit when worked by hand. An interesting example of this is shown in a Paper read by Mr. Kirkup to the Colliery Managers' Association. The seam referred to is a very hard seam of steam coal, about 26 in. thick, with a fairly bad roof. When worked by hand the underground cost of production was 5s. 1½d. per ton, while when worked by a coal-cutter the cost was reduced to 4s. 6½d. per ton, including capital charges and repairs on the cutter. This shows a clear saving of 7d. per ton, besides the fact that the value of the coal was increased enormously, due to the much larger percentage of round coal produced.

Another branch of the mining industry into which electricity enters very largely is the hauling of the coal from the inner workings to the pit bottom. The two methods generally used before underground haulage gears were installed were haulage ropes underground driven by steam gears on the surface, and haulage by horses, hundreds of which were sometimes to be found in one pit, representing a great outlay of capital. Neither of these systems was found to be economical; the first because of the enormous wear and tear on ropes and the great lengths of rope in the shaft doing no useful work, and the

*Abstract of a Paper read before the Rugby Engineering Society.

Digitized by Google

second because of the additional cost of keeping roads at a height of at least 5 ft. to allow the horses the necessary head room.

Three types of haulage gear are used to suit the different conditions existing. These are :—*Main Rope Haulage.*—This system is adopted where the road to be worked is a single one, and where there is sufficient gradient to allow of the tubs running back by gravity. The type of motor which is used for this class of gear is the compound motor if the supply is direct current, or the slip-ring motor if alternating current is in use. The motor has always to start up against a considerable load, and it is essential that motors used for a main-rope haulage should be capable of starting up slowly, since, if the gear is started quickly, the rope and the tub couplings will be subject to severe shocks—thus the cost of maintenance would be heavy. For large gears, the maximum speed of the rope would probably be from 8 to 12 miles per hour. *Main and Tail Haulage.*—This type of gear is used frequently for fairly level loads, where the empty tubs will not run back by gravity. The arrangement is that the rope, which is run round a loose pulley at the end of the haulage road, has one end attached to the train of tubs for pulling, while the other end is attached to the back of the train, so that where there is a down gradient at any point the tubs can be retarded. Here again a considerable starting torque may be required and slip-ring motors are generally installed. Both types of haulages are frequently driven direct through gearing from the motor, but many engineers prefer belt or rope drives, which, to a great extent, absorb severe shocks on the gear, due to the tubs becoming derailed. Liquid starters are frequently used for this work, and are found to be very satisfactory, as it is possible to speed up gradually, thus reducing the shock on the rope. *Endless Haulage.*—This type of gear is used very extensively on long double roads. It is generally arranged to run at $1\frac{1}{4}$ to $2\frac{1}{2}$ miles per hour, according to circumstances, and has the great advantage over the other two systems that it provides a practically steady load all day while the other types take a very varying load. Another advantage is that with this type of gear a squirrel-cage motor may be used. This is usually arranged to drive the gear through a friction clutch, so that the motor may be run up to speed on light load only, the friction clutch being gradually tightened, and the gear started afterwards.

The following figures may serve to show the great economy which can be effected by the installation of electric haulage gears underground over the surface haulage system. The length of road is 500 yds. the haulage is of the endless type with a rope speed of $1\frac{1}{8}$ miles per hour, and the power absorbed is about 33 H.P. The total output is 300 tons per day, and the cost of working it is found to be 0·39d. per ton. Originally this road was worked by a steam haulage gear on the surface, and the working cost was found to be 1·77d. per ton. This shows a clear gain of 1·38d. per ton, which with this output means a saving of about £500 per annum. Electric locomotives are used to some considerable extent on the Continent for underground work, but there are very few in operation in this country, probably because of the stringent mines regulations existing. They are only suitable for use in roads exceeding 6 ft. in height, and, of course, can only be used in roads which are ventilated with fresh air, that is for roads near the downcast shaft, on account of the considerable amount of sparking at the collector.

HARMONIC ANALYSIS DIAGRAMS.

BY R. BEATTIE, D.Sc.

(*Concluded from page 328.*)

Accurate Determination of Higher Harmonics.—Diagrams of reciprocal-sine scales with a limited number of ordinates—say 12 for instance—cannot, of course, give the higher harmonics with the same degree of accuracy as the lower. To do this the diagrams for the higher harmonics would have to be constructed with an increased number of ordinates to correspond to the order of the harmonic sought; whilst this is in general inexpedient, it may be pointed out that by the expenditure of a little extra labour a diagram of few ordinates can always be used in such a way as to be practically equivalent to a diagram of many ordinates.

Thus, let it be desired to determine accurately the resultant 5th component by means of the 12-ordinate diagrams of Figs. 2 and 3. The curve to be analysed is supposed to be drawn on tracing paper as before, but it must now be extended to the left of the origin for a distance of at least one-twelfth the wave length. This tracing is first placed on the diagrams, Figs. 2 and 3, so that the origin coincides with S_1 or C_1 as the case may be. The intercepts are then read off on the several scales, added up, and the sum divided by half the number of ordinates, precisely as already described. Let the values so obtained for the sine and cosine components be denoted by A_5 and B_5 respectively.

The tracing of the curve is next shifted to the right, and parallel to the base, through a small distance x, where x is some aliquot part—say, one-quarter—of the distance between successive scales, so that $x = S_1S_3/48$. As before, the intercepts are read off and added, the new values thus deduced being denoted by A_5' and B_5'.

Similarly, let A_5'', B_5'' denote the respective values obtained for the sine and cosine coefficients when the tracing is shifted a total distance $2x$ to the right, and A_5''', B_5''', the values when the tracing is shifted a distance $3x$ to the right.

We have thus four independent determinations of the sine and cosine coefficients at our disposal. The corresponding resultant components deduced from these are, $\sqrt{(A_5)^2+(B_5)^2}$, $\sqrt{(A_5')^2+(B_5')^2}$, $\sqrt{(A_5'')^2+(B_5'')^2}$ and $\sqrt{(A_5''')^2+(B_5''')^2}$, respectively, the mean of which may be taken as the most probable value of the resultant component.

To deduce the phase of the resultant component, it should be observed that $\tan^{-1}(B_5/A_5)$ gives one value of this, $\tan^{-1}(B_5'/A_5')+x$* a second, $\tan^{-1}(B_5''/A_5'')+2x$ a third, and $\tan^{-1}(B_5'''/A_5''')+3x$ a fourth. The mean of these four quantities is certain to be nearer the correct value of the phase than any one of the individual determinations.

Used in this way a diagram of 12 ordinates is substantially equivalent to one of 48 ordinates.

Reciprocal-sine Curves.—A wider degree of generality, though possibly a somewhat less practical character, may be given to the diagram of reciprocal-sine scales in the following way. Imagine a large number of scales to be introduced (say, into Fig. 2, for example) each scale being graduated on the reciprocal-sine principle. Let the corresponding points of division on these scales be joined by continuous curves, the linear scales being at the same time omitted and the curves numbered instead. The loci thus obtained have the shape shown in Fig. 4, and constitute a family of "reciprocal-sine" curves corresponding to the general equation $y = \pm k/\sin n\theta$. Fig. 4† is, in fact, the graph of this equation obtained by giving the parameter k the successive values 0·2, 0·4, 0·6, &c., up to 3·8, the distance S_1S_3 being taken to represent 360 deg. and n being put equal to 2.

Obviously such a diagram can be used for the purposes of harmonic analysis in place of a diagram of reciprocal-sine scales—Fig. 4, for instance, gives the second sine component—and it has the advantage over a diagram of reciprocal-sine scales of being applicable for just as few or just as many ordinates as circumstances may demand. The curve to be analysed is first drawn on tracing paper so that the wave-length is equal to S_1S_3. The base of the curve so drawn is next divided up into any convenient number of equal parts according to the degree of accuracy required, and ordinates are erected at the middle points of the several divisions. The tracing paper carrying the curve and its ordinates is then placed on the diagram of reciprocal-sine curves, as in Fig. 4, so that its base coincides with S_1S_3, and the lengths of the various ordinates (shown dotted) are read off by help of the curves. Thus, in Fig. 4, the successive ordinates are: +0·16, +1·32, +1·85, −1·45, −2·96, −1·57, +1·00, −0·50, −1·45, +1·25, +1·50, +0·20. The algebraical sum of these, divided by half the number of ordinates, is −0·19, which is, therefore, the value of the second sine component of the curve represented. To obtain the value of the cosine component it is only necessary to shift the tracing paper parallel to the base through a distance S_1C_1 (representing 90 deg. on the scale of the second harmonic) and proceed as before. In analysing symmetrical curves, such as alternating-current wave-forms, the half-wave trace is placed on S_1S_2 to get the sine component, and on C_1C_2 to get the cosine component.

* The displacement x must be expressed in angular measure on the scale of the 5th harmonic; thus, in degrees, $x = 5 \times 360/48$.

† For preparing Fig. 4 I am indebted to Mr. Harold Gerrard, M.Sc.

Digitized by Google

Whilst being a distinct improvement from the point of view of general adaptability, diagrams of reciprocal-sine curves are, it must be admitted, inferior to diagrams of reciprocal-sine scales in most other respects. They are more troublesome to construct, less easy to read, and to be accurate the diagrams must contain so many curves that they become overcrowded to an impracticable degree, more especially the diagrams for the higher harmonics. As an aid to analysis, the use of diagrams of reciprocal-sine curves can hardly be recommended therefore. It is hoped, however, that a set of diagrams of reciprocal-sine and reciprocal-cosine scales may prove of some general utility as a simple kind of harmonic analyser when the services of one of the more elaborate forms of mechanical analysers are not available.

Modified Diagrams of Reciprocal-sine Scales.—Certain modifications of the reciprocal-sine diagrams will probably suggest themselves to the reader. Thus we might wish to render the diagrams applicable when the function y is not in the first instance obtained as a continuous curve, but only the numerical values of the function at a number of regular intervals throughout the period are given. To save the labour of actually plotting the graph of y from these numbers we might employ a diagram like Fig. 5. This is a combination of Figs. 1 and 2, each ordinate being provided on one side with graduations on the reciprocal-sine (or reciprocal-cosine) principle, and on the other side with a normal scale. To illustrate the method of using this composite type of diagram, suppose that the successive mean monthly values of a certain variable with a yearly period are, +3·4, +4·1, +3·3, +1·1, +1·8, +3·0, +3·8, +3·6, +2·7, +1·5, +1·7, +3·2. Then we have only to read off these respective values on the right-hand scales of the first, second, third, &c., ordinates of Fig. 5 (reckoning from S_1 to S_3), and note at the same time the corresponding readings on the left-hand scales, viz., +3·81, +2·95, +0·87, +0·30, −1·29, +2·88, −3·68, +2·64, −0·70, −0·40, +1·20, −3·10. The sum of these latter numbers when divided by 6 gives −0·18, which is therefore the value of the fifth sine component of the variable under consideration.

Sine-scale Diagrams.—Another possible construction for a harmonic analysis diagram may also be mentioned, in which the unit of a vertical scale at a distance θ from the origin instead of being made equal to $\pm 1/\sin n\theta$ (or $\pm 1/\cos n\theta$) is made equal to $\pm \sin n\theta$ (or $\pm \cos n\theta$). A diagram of this kind—such as that shown in Fig. 6, which represents a "sine scale" diagram for determining the fundamental sine component—is evidently adapted for use in conjunction with a planimeter. Thus, take a wave-form whose true shape as ordinarily drawn in rectangular co-ordinates is that of the curve in Fig. 1. To prepare this curve for analysis it must be re-drawn on the diagram of Fig. 6, when it becomes distorted in the manner shown. If we now measure the area of the closed loop $S_1LS_2MS_3S_2S_1$ by means of a planimeter and divide by half the base-length of the diagram, the quotient obtained is clearly equal to twice the mean value of $y \sin\theta$, and is, therefore, the required coefficient of the fundamental sine component.

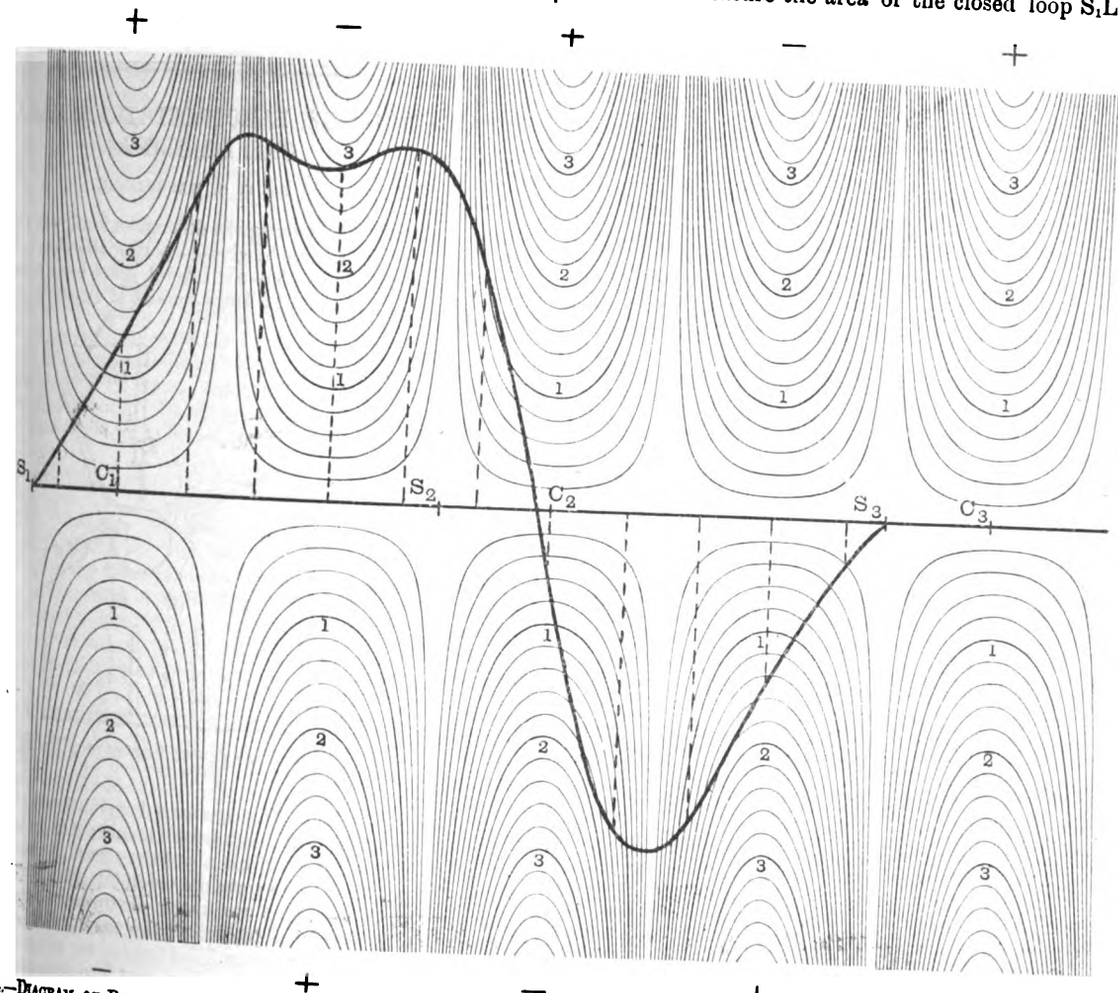

Fig. 4.—Diagram of Reciprocal-sine Curves for Determining the Coefficients of the Fifth Sine and Fifth Cosine Terms.

This type of harmonic analysis diagram has been referred to, not because it is likely to prove more useful than diagrams like Figs. 2 and 3, but because it is the complementary construction to that employed by Slichter,* whose diagram consists of a series of vertical ordinates normally divided but spaced at irregular intervals, the distance between any two consecutive ordinates at a mean distance θ from the origin being made proportional to $\sin\theta$. Both Slichter's method and that requiring the use of diagrams like Fig. 6 are tedious, however, because they involve the re-drawing of the curve to be analysed just as often as there are components to be determined. Hence, although the sine-scale diagram can be made to yield results of con-

* *Loc. cit.*

Digitized by Google

siderable accuracy, the time required in using it is likely to militate against its general adoption. For this reason it has been given no more than a passing mention, and it is left to the ingenuity of the interested reader to work out for himself the

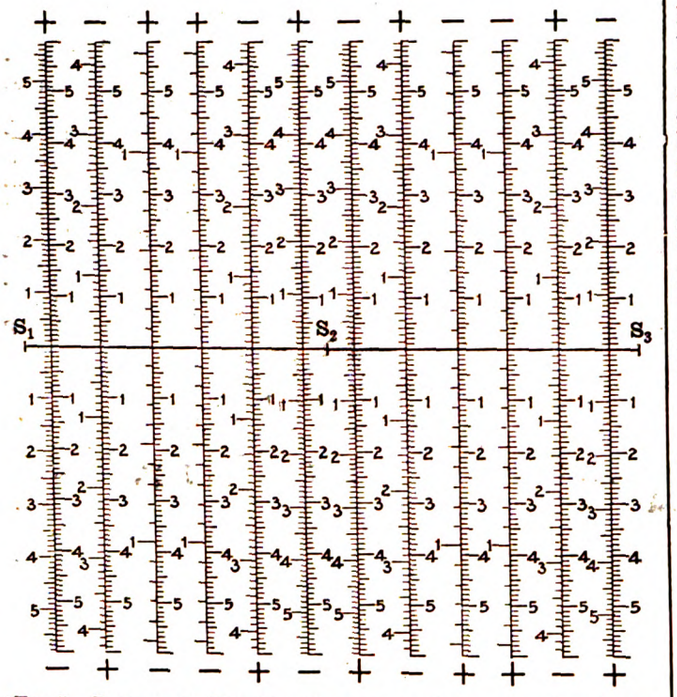

FIG. 5.—DIAGRAM OF COMBINED UNIFORM AND RECIPROCAL SINE SCALES FOR DETERMINING THE COEFFICIENT OF THE FIFTH SINE TERM.

The attached signs refer to the left-hand scales; the right-hand scales are to be taken as positive above the base line and negative below.

details of the various adaptations of which the diagram is capable. It will be seen at once, for example, that it is unnecessary to employ the complete diagram as drawn in Fig. 6.

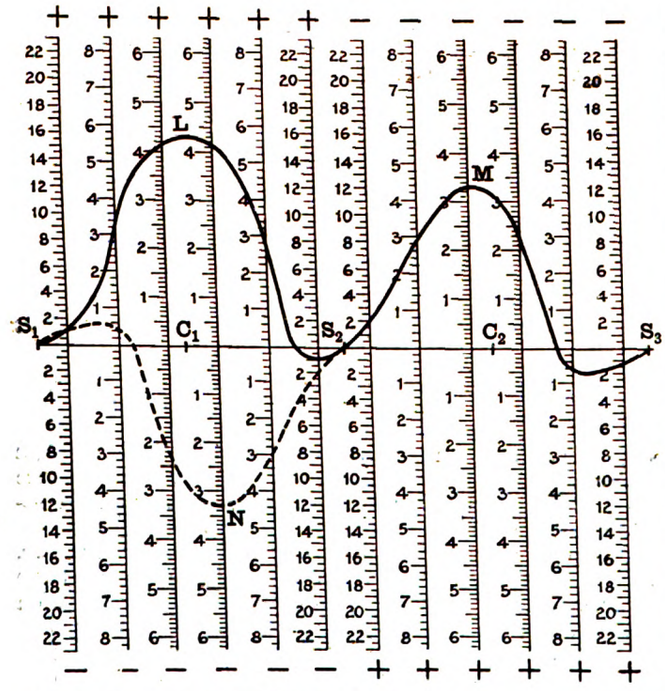

FIG. 6.—DIAGRAM OF SINE SCALES FOR DETERMINING THE COEFFICIENT OF THE FUNDAMENTAL SINE TERM.

For if we employ the first half of the diagram only, and plot on this the first half of the curve to be analysed, going forward from left to right, and the remaining half of the curve coming backward from right to left, then the result of carrying the tracing point of the planimeter round $S_1LS_2NS_1$ (the closed loop obtained by this method of plotting) is the same as carrying it round $S_1LS_2MS_3S_2S_1$.

Further, the half diagram S_1S_2, Fig. 6, suffices for any given higher sine harmonic as well as for the fundamental. Thus, if we wish to obtain, say, the 3rd sine component, let the base of the curve to be analysed be divided up into 6 equal parts, and let the first section of the curve be plotted on the half-diagram S_1S_2 from left to right, the second section of the curve being plotted backwards from right to left, the third section from left to right, and so on. The reading of the planimeter after it has been carried round the closed curve thus traced gives, when divided by three times the length of the base S_1S_2, the required 3rd sine component. The corresponding 3rd cosine component is found by using the part of the diagram lying between C_1 and C_2 instead of that lying between S_1 and S_2.

It is instructive to compare a diagram of sine-scales employed in this way with the Clifford-Perry,* Clifford-Finsterwalder† and Wedmore‡ diagrams.

APPLICATIONS OF ELECTROSTATIC SEPARATION TO ORE DRESSING.§

BY F. S. MACGREGOR.

The possibility of utilising the differences in the electrical conductivity of various minerals by giving a part or all of the particles of ore an electrostatic charge has for several years been recognised as a means of separation, and a large amount of experimenting has been

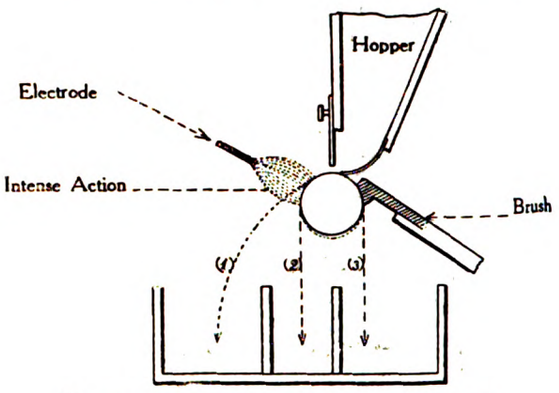

DIAGRAM OF ELECTRICAL SEPARATING MACHINE.

done along this line. The commercial application of the art of ele trostatic separation has been tried a number of times within the la decade, but until only within about three years has success attend the efforts. Two factors contributed to this want of success—a la of the proper means of continuous electrification, and a practic machine and system of treatment designed to meet the rigorous r quirements of mill operation.

Several types of separators have now been perfected, and in th Paper is described a means of electrification which has been a co mercial success from its first installation.

The type of machine employed is shown in the accompanyi diagram. It consists of a series of separating electrodes placed c above the other. The frame is cast-iron, built in sections, with t electrodes to each section, which facilitates easy shipment and a flexibility in the number of treatments which can be given the c A three-section machine (the usual type) is 6 ft. high, 6 ft. 6 in. l and 18 in. wide. A feed hopper on the top distributes the ore acr the first electrode, and it passes by gravity to each succeeding o The mineral particles receive their charge while passing throug concentrated static field formed by two electrodes—one an earth rotated shaft, and the other an insulated metal rod. sand volts, or an intermittent charge of great regularity. The strength of the field can be altered at will, according to the conductivities of various ores treated. The figure shows the scheme of separation, the dotted lines indicating the path of the conductors and non-conductors.

The separating plant at Platteville was started in March, 1908, and was the first plant to be equipped with Huff separators. Although originally built as an experimental plant, it has been in practically continuous operation since then, and is used to separate, without roasting, the iron pyrites from the zinc blende, which occur together in varying proportions in south-western Wisconsin. The ores are milled in ordinary jigs and the lead and lime rock removed. Owing to the nearness in specific gravity of the blende and pyrites, they are recovered in the jigs as middlings, containing from 10 to 45 per cent. zinc, according to the grade of the crude ore, the remainder being iron and the sulphur in combination. Iron above a few per cent. interferes with the smelting of the blende, and the function of this plant is to remove this impurity, making the low-grade ores into high-grade smelting ores.

The plant consists of a wooden frame building, 30 ft. by 40 ft., and three stories high. On the first floor are the bins for collecting the finished products as they are delivered from the separators. The second and third floors are separator floors, and in the tower is located the screening system. A spur railroad track runs on either side of the mill, one for cars of raw ore, allowing them to be unloaded either directly into the mill or into storage bins across the track. The other track, which is below the mill level, permits at the same time the loading of empty cars with finished products.

The course of the ore through the plant is as follows: It is shovelled into a wheel-barrow in the freight car, wheeled to scales and weighed, then dumped into the feed hopper of the dryer. The top of this hopper is on a level with the car floors to facilitate the easy handling of the ore, and at the bottom of this hopper is an adjustable plunger feeder. The dryer is of the cylindrical type, and the shell is 16 ft. long and 30 in. in diameter, rotating about 4½ revs. per min. Being set at a slight pitch, the ore travels gradually to the discharge end, where it emerges bone dry. As the separation depends on the difference in conductivity of the minerals, it is necessary that all moisture should be removed.

A short drag conveyor carries the dried ore to the foot of a bucket elevator, which raises it to the top of the tower and discharges it into a set of screens. There are four giving an oversize, and four other sizes, called A, B, C and D. The oversize passes through a short trommel to remove any foreign materials, and is spouted to the first roll to a set of rolls, which crush it and deliver it to the boot of the elevator carrying the original feed.

The location of the screens in a tower permits the different sizes to flow by gravity through an iron pipe 2 in. diameter to the top machine floor. On this floor are placed the rougher machines, where the ore is given a rough split, that is, two products are made, one a product higher in zinc than the original feed, and the other higher in iron. Thus, no matter what the grade of the feed to the mill may be (and it varies within wide limits), a fairly uniform mixture is sent to the finishing machines on the floor below.

These finishing machines give the final cleaning to the ore, one set giving a finished iron product, and the other a finished zinc product. The middlings from these cleaners return by gravity to the boot of the elevator and mix with the fresh ore, so that no ore leaves the system that is not separated into its proper grades of product. The finished zinc product and finished iron product fall into separate bins on the first floor. These bins are V-bottomed, and constructed of two thicknesses of wood flooring with heavy building paper between. They are elevated from the floor so that they may conveniently be drawn off into a 1,600 lb. capacity push-car for loading. The car is then wheeled to a small elevator and dumped into a hopper on the floor level. This feeds the ore into the boot of a small elevator, which discharges either into a freight car by means of a goose-neck spout, or may be allowed to discharge to a second elevator in the storage bins. From these bins a car may be loaded whenever convenient.

Two products of marketable value are obtained: the iron pyrites, heretofore valueless in these Wisconsin ores, is sold for its sulphur content, and by reason of its free-burning qualities, makes a very desirable product for the acid manufacturer; and a zinc product which, of course, sold for spelter. The pyrite is sold by contract, but the blende is sold to the smelters on the open market. With a penalty for excess of iron or lead it is evidently necessary for such a plant to turn out consistently high-grade products in order to command a satisfactory market price.

As a result of the excellent showing of this electrostatic plant, the United States Smelting, Mining and Refining Co. decided to put in a plant at their works at Midvale, Utah. The function of an electrostatic plant there is different from that in Platteville, for the ore from the mine of the United States Company at Bingham, Utah, contains about 9 per cent. of zinc in addition to the gold, silver and lead values. This ore is shipped to the concentrator at Midvale, where it is crushed and milled by the usual methods of jigs and tables. In this concentration there were formerly two products, one a lead-pyrite product carrying the iron and considerable zinc, and a tailings carrying zinc and some gold and silver values, the object being to keep the zinc as low as possible in the lead concentrate, and yet at the same time make the maximum recovery of the gold, silver, lead and copper values. The zinc added materially to the difficulty and cost of smelting the lead concentrates, and, at the same time, was a total loss. In order to recover this zinc, three products were made in the concentrator, lead-pyrites carrying practically no zinc, tailings free from zinc, and middlings containing about 22 per cent. zinc, the balance pyrite and some copper, lead, gold and silver.

To treat these middlings, an electrostatic plant was built near the concentrator as shown. It is a wooden frame building, 40 ft. by 40ft., and covered with corrugated sheet-iron. In general plan it is the same as the Platteville plant—finished ore bins on the ground floors, and two floors of separators. The method of handling the ore is somewhat different. The middlings are shovelled from the table hutches in the wet concentrator into tramcars, which are pushed by hand to the platform elevator at the electrostatic plant. The cars are raised to the third floor level, and, after weighing, are dumped into a 40-ton hopper. This is built over the dryer, and feeds automatically. After drying, the ore is screened. The oversize is small in amount and very low in zinc, so instead of re-crushing, it is put directly into the finished pyrites. The three sizes are separated, and the products drawn from the bins on the first floor into tramcars. These are run out of the mill to the loading trestle and dumped into freight cars. The pyrite product is smelted near by, and the zinc product is shipped to the Kansas zinc smelters.

The plant is electrically-driven by a 20 H.P. motor, the 15 Huff separators requiring about ⅓ H.P. each. The generating apparatus for the electrostatic field is located in a small room on the finishing floor. A 3 H.P. motor is direct-coupled to a generator, and the strength of field is controlled from a small switchboard. This electrostatic plant not only removes the objectionable zinc from the lead-pyrites concentrate, but makes it a marketable product, and, instead of being a total loss, it is made to produce a profit. The electrostatic process in these two plants demonstrates two applications in ore dressing, one the custom plant making low-grade ores profitable, and the other as an adjunct to a wet concentrator for the recovery of zinc. Besides these plants, there is being installed in Nevada a plant working on crude silver ores, wherein the ore goes through no concentrating machinery prior to its electrostatic treatment.

EXPERIMENTS IN IMPACT EXCITATION.*

BY G. W. NASMYTH.

Summary.—In the first section of this article the author shows that the Lepel arc has a falling characteristic much steeper than those of the Duddell and Poulsen arcs and operates on smaller currents. By plotting P.D. against arc length a resonance phenomenon was suggested, and the maxima observed in the voltage were found to be due indirectly to the changing capacity of the arc itself, being caused by corresponding minima in the oscillations produced by the arc. In the succeeding sections, on the intensity and frequency of the oscillations, it is shown that the minima in the oscillations occur at larger values of the direct current through the arc as the capacity in the shunt circuit is increased or the inductance diminished, and that the intensity of the oscillations increases. It is also shown that the frequency of the oscillations increases with the arc current and decreases with the arc length, and that the formula derived by the author for the frequency of the singing arc holds true also for the frequency of the oscillations produced by the new short arcs between metal electrodes.

The Characteristics of Short Arcs between Metal Electrodes.

The author first reviews briefly the history of "impact excitation" since October, 1906, when Wien published a short account of his experiments. In the same year Lepel† began his work on the discharge between metal electrodes. By September, 1907, Lepel's apparatus had been so perfected that he was able to transmit mes-

sages and musical tones from Slough to Scheveningen, 160 miles, using an E.M.F. of 440 volts and 1·5 amperes of direct current.

The first public announcement of any of the short spark methods of generating oscillations was made by von Arco* in April, 1909. The Telefunken Co. had experimented with Lepel's apparatus early in 1907, but finding it unsatisfactory in its form at that time proceeded to develop its own system. Recently Prof. W. Peukert† has announced the invention of a short spark generator in 1906, for which a patent application was filed February, 1907, prior to either the Lepel or Telefunken Co. applications.

These three short spark generators constitute the chief means at present available for producing high-frequency oscillations of the impact excitation type. In principle the three spark generators have much in common, and experiments and theory dealing with any one will have a measure of value for each of the others. The author's experiments have been made on the Lepel generator. This is the simplest of the three, since it uses direct current instead of alternating, as in the case of the Telefunken generator, and it has no moving parts, as in the case of Peukert's apparatus.

Arc or Spark.—The discharge between the electrodes of all three generators is intermediate in character between the ordinary arc and spark discharges, and in the absence of exact definitions for the two terms it is difficult to decide in which class they should be placed. From the arc point of view, Lepel's generator is a direct-current arc between metal electrodes, the Telefunken arrangement is an alternating-current arc, and Peukert's generator is an arc between relatively rotating electrodes. But in general, when the capacity circuit is connected, the discharge of all three generators becomes discontinuous, and corresponds to a spark-gap. This condition also arises in the Poulsen arc, although to a less extent. Von Arco has suggested the following definitions: "By arc excitation one might understand that method of producing oscillations by which the rate of condenser discharges is equal to or about the frequency of the oscillations; by spark excitations, that method by which this rate is considerably less." This definition makes the type of discharge depend upon the constants of the circuit, and the same generator might be an arc or a spark-gap under different conditions. The author's experiments on the Lepel generator have demonstrated that in many of its general characteristics it bears a marked simi-

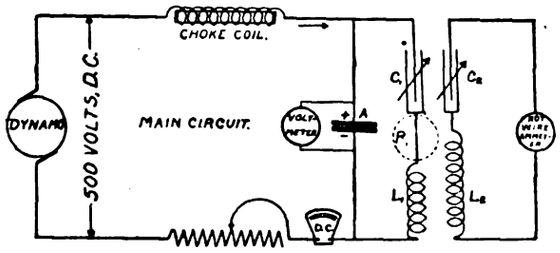

FIG. 1.—DIAGRAM OF CONNECTIONS.

larity to the Poulsen arc, and for the present it will be called an arc whenever the applied voltage would be sufficient to maintain the current through the gap if the condenser circuit were disconnected.

Besides the familiar damped discharge of the ordinary spark-gap, three distinct types of arc oscillations have been recognised quite generally by investigators in this field. For convenience the author has named these types after the experimenters who first produced them—viz., Duddell, Poulsen and Wien. The characteristic of the first class of oscillations is that the maximum value of the condenser current is less than that of the direct current through the arc, so that the arc remains lighted. In the second the maximum value of the condenser current is greater than that of the direct current through the arc, so that the arc is extinguished and re-lighted at each oscillation, whilst in the Wien oscillations the maximum value of the condenser current is so great that the arc is not only extinguished, but is re-lighted in the opposite sense. It is with these oscillations that this investigation is chiefly concerned.

Arrangement of Experimental Apparatus.—In the author's experiments on the Lepel arc the arrangement of apparatus is shown in Fig. 1. The source of E.M.F. was a 500-volt shunt-wound dynamo, direct connected to a two-phase 900 revs. per min. induction motor. A large water rheostat made from an old oil barrel, together with two Cutler-Hammer rheostats arranged for connection in series or parallel, each having a maximum resistance of 200 ohms and a current capacity of 1·5 to 2·5 amperes, constituted the resistance in the circuit. The choke coils were two solenoids, each of 0·0296 henry. In the condenser circuit a variable number of Leyden jars, having a capacity of 0·00188 mfd. each, were connected in parallel. A Weston direct-current voltmeter of the d'Arsonval galvanometer type, with a 600-volt and 150-volt scales, was connected across the arc, and a Weston millivoltmeter, with a 5-ampere shunt, was connected in series with the main circuit, as shown. The intensity of the oscillations was measured by an unshunted hot-wire ammeter containing no iron and giving a maximum deflection at 7 amperes of direct current. The position of the ammeter when used for measuring the oscillations is shown by the dotted circle in the primary circuit.

After experimenting with various forms of the Lepel apparatus, it was found that with flat copper plates water cooling of the electrodes was unnecessary, as the radiation to the air was large, and the generator seemed to work better, if anything, as it became heated by the discharge. The author's first experiments were made with brass and copper plates. The results obtained when either metal was used as cathode were fairly satisfactory, but the pitting of the brass plate, due possibly to the volatilisation of the zinc, was found to be a source of great annoyance and to make the oscillations inconstant by changing the arc length. Two electrodes of sheet

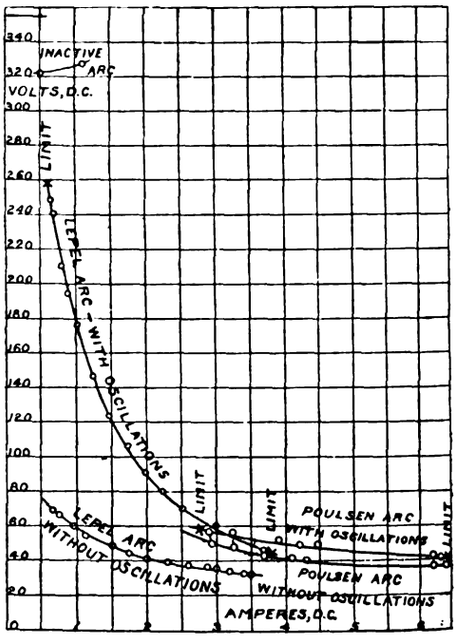

FIG. 2.—COMPARISON OF LEPEL AND POULSEN ARC CHARACTERISTICS.

copper ¼ in. thick and 6 in. in diameter were then obtained. These were carefully surfaced in a lathe with a sharp tool set at an acute angle, and were then rubbed with sandpaper and oil. The connecting wires were at first soldered to the copper plates, but after they had been melted off two or three times they were fastened to screws set into the edges of the plates. These electrodes were found very satisfactory. The oscillations are more irregular when the surfaces of the electrodes have been rubbed with emery cloth than when oil and a sandpaper block are used. On the other hand, the vapour of the oil (ordinary machine lubricating oil was used) seemed to have a marked effect in steadying the arc conditions.

Very good electrodes may be made from the hard rolled copper plate used in the photo-engraving processes. The surface of this copper is very smooth and flat, and it holds its shape well on account of its hardness. If this copper sheeting is used, it is unnecessary to turn the plates to a flat surface in a lathe. The plates need only be rubbed with fine pumice stone and oil, and then with a piece of wood carbon and oil, and the surface is almost perfect. Contact with the connecting wires may be made by means of a piece of tinfoil held down by a small weight.

Any kind of paper seems to work well as an insulator and as a source, when disintegrated by the discharge, of the hydrogen and carbon atmosphere which the arc requires for satisfactory working. For the sake of uniformity in conditions, W.S. & B. Paragon typewriter paper in legal size sheets was used in all the quantitative experiments. In thickness this paper is very closely 0·05 mm. per sheet. Mica rings were tried without success, as the discharge occurred either at the edge of the mica, or, if this were prevented by cutting a sufficiently deep groove in the plates, the discharge took

Digitized by Google

place through the mica instead of across the air-gap. To start the arc various devices may be used, the most convenient one being to short-circuit the arc and then suddenly break the short-circuit with an oil switch, thus bringing the full pressure of the inductive kick of the choke coils to bear on the gap. If the edge of the hole in the paper has been charred, by a match or some other means, the discharge will start as soon as the P.D. is applied.

As in the case of the Poulsen arc, the Lepel generator may be made to give increased power by connecting several arcs in series. By starting the arcs one at a time separately and then connecting them together in series the author has been able to make as many as three arcs run on 500 volts impressed E.M.F. This was only possible at relatively large currents, however. A better way to obtain increased power at a given impressed E.M.F. is to connect two arcs in parallel, each with its own choke coil and resistance in series.

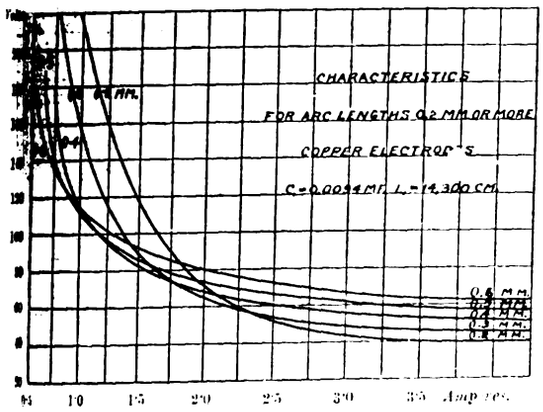

FIG. 3.

The method of generating oscillations by connecting arcs in parallel in this way was discovered by the author in 1907, set forth under the title "An Improved Form of the Duddell Singing Arc."* Later the attention of the author was called by Mr. Duddell† to a lecture given in England before the Institution of Electrical Engineers, in which practically the same principle had been used. The author had overlooked the reference to the earlier work, and is glad to take this opportunity of acknowledging the priority of Duddell in discovering the method of generating oscillations by connecting arcs in parallel.

The characteristic Lepel curve for an arc length of 0·15 mm. when the arc is generating oscillations is shown in Fig. 2. For currents much larger than 4 amperes the arc becomes inactive and the oscillations cease, probably on account of the flatness of the curve for large currents. For currents less than 0·7 ampere it is difficult to obtain steady conditions on account of the steepness of the curve. The readings of the direct-current instruments are, of course, average or integrated values.

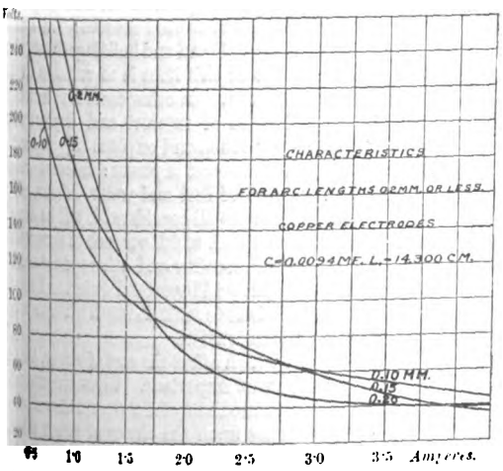

FIG. 4.—LEPEL ARC CHARACTERISTICS FOR DIFFERENT ARC LENGTHS.

The relation of the Lepel arc characteristics to those of the Poulsen arc are also shown in Fig. 2. The lower curve for the Lepel arc gives the corresponding characteristic when the condenser circuit is disconnected. One reason for the greater effectiveness of the Lepel arc is due to the steepness of the characteristic in the region of small currents in which it operates. Even at larger currents, however, the Lepel characteristic seems to be much steeper than that for the Poulsen arc. The separation of the two curves is also seen to be much greater than that for the Poulsen arc. The product of the difference of the voltages of the two characteristics by the corresponding amperes may be taken as a measure of the power converted into oscillations. Since the characteristic "without oscillations" varies but little for the different arc lengths, a comparison of the characteristics "with oscillations" will furnish a means of finding the arc length and current which will transform most power into oscillations and give the greater efficiency. It was found that with the author's apparatus the maximum power and efficiency are obtained at an arc length of 0·2 mm. and with a current between 1·0 and 1·5 amperes.

In attempting to find the change in the characteristic curve when the arc length was varied, apparently discordant results were obtained. For large currents the voltage increased with increasing arc length, as in the case of the Poulsen arc, but for small currents the voltage sometimes increased and sometimes decreased with increase of arc length. It was then decided to make a systematic exploration of the whole characteristic field, taking a hundred or more observations at each arc length under different conditions and at different times, and drawing a smooth curve through the observations. The results of these experiments are shown in Figs. 3 and 4, representing more than a thousand single observations. It is evident from these curves that for small currents (*e.g.*, 1 ampere) as

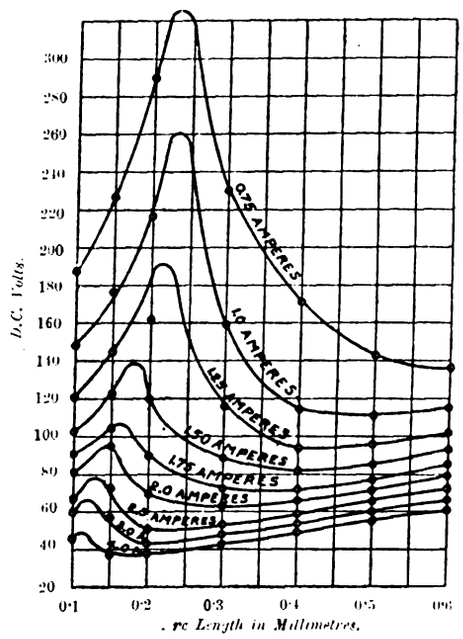

FIG. 5.—P.D. ACROSS ARC FOR CONSTANT CURRENT AND VARYING ARC LENGTH.

the arc length is increased from 0·1 mm. to 0·2 mm. the voltage increases; then as the arc length is increased to 0·5 mm. the voltage falls off rapidly at first, then more slowly, and begins to rise again as the length is increased to 0·6 mm. If cross-sections of the curves are taken in this way at constant currents, and the P.D. across the arc plotted against the arc length, the family of curves shown in Fig. 5 is obtained.

This suggested a resonance phenomenon, and tests were at once made to determine whether the effect was a true one corresponding to something inherent in the short spark form of excitation, or a false effect due to some peculiarity in the measuring instruments. The substitution of another voltmeter, and, moreover, its high resistance, precluded the possibility of resonant oscillations through the voltmeter. The clue to the cause of the phenomenon was obtained accidentally, and it was suspected that the curious variations in the arc voltage as the arc length was increased might be due to the change in the capacity of the arc as the distance between the plates was varied. A rough computation, using 1 as the dielectric constant of the paper and gas between the plates, showed that the capacity of the arc varied between rather wide limits, from 0·0016 mfd. at 0·10 mm. arc length to 0·00023 mfd. at 0·70 mm. Accordingly, a variable air condenser was connected directly across the arc, and the values of the arc voltage and oscillation current were read as the capacity in parallel with the arc was varied. The

arc length used was 0·25 mm. and the direct-current ammeter reading was maintained constant at 2·5 amperes by varying the resistance in the main circuit. The results are shown in Fig. 6.

In Fig. 6 the variable capacity in parallel with the arc is plotted as abscissa, with the direct-current voltage across the arc and the corresponding intensity of the oscillations indicated by a hot-wire ammeter as ordinates. The capacities corresponding to arc lengths of 0·05, 0·10, 0·15 and 0·20 mm. have been marked, and the left-hand boundary of the figure, with no capacity in parallel, corresponds, of course, to the arc length of 0·25 mm. actually used. The resistances in series with the arcs have not been plotted, but the resistance curve is approximately the reciprocal of the voltage curve.

It is apparent that the voltage curve with varying arc capacity corresponds qualitatively at least with the voltage curve for varying arc length at 2·5 amperes shown in Fig. 5. The maximum in the voltage in Fig. 5 occurs at an arc length less than 0·15 mm., while in Fig. 6 the maximum occurs at a capacity equivalent to an arc-length slightly more than 0·15 mm., as calculated. The discrepancy is due in part to the manner in which the plates forming the arc electrodes were arranged in the two experiments. Further experiments showed that the maxima observed in the voltage in Fig. 5 are due chiefly to the changing capacity of the arc itself, as the arc length is varied, and that corresponding to these maxima in the voltage there are minima in the oscillations produced by the arc.

At small capacities the condensers will charge up quickly, the number of discharges per second will be great, and the sparking potential will be low, since the gas will remain ionised to a large extent. The intensity of the oscillations, as measured by a hot-wire ammeter, will be large, and the average direct-current voltmeter reading low, partly on account of the low sparking potential, and partly because the charging time, when the voltmeter reading is obtained, is relatively small compared with the discharging time,

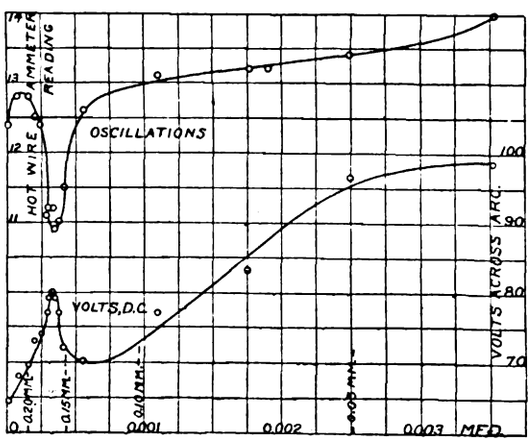

Fig. 6.—Effect of Arc Capacity on Arc Voltage and Oscillations.

when the voltmeter indication should be relatively small. At large capacities, on the other hand, the quantity of energy liberated at each discharge is large, the trains of oscillations will last a long time, and their effective value will be large even though the number of discharges per second is relatively small. A large reading of the hot-wire ammeter should, therefore, be obtained. But the resistance of the arc will be small while the large current is flowing through it, and the time of each discharge is large compared with the time of charge. In this case also, then, the average voltmeter reading will be small. Between these limiting cases a low value of the oscillations may result from a low value of the group frequency, due to high sparking potential, and a low value of effective oscillation current, due to small capacity. The time of charge will be relatively great and the time of discharge relatively small, giving a large value of the average voltmeter reading. The minimum in the oscillations should correspond with a maximum in the voltage, therefore, and this effect is observed in Fig. 6.

The reason for the shift of the maxima into the region of larger arc capacities as the current is increased is clear from this explanation. If the direct current from the generator is increased, the time required to charge the condensers will be decreased. This is the same effect as would be produced by a decrease of capacity. To neutralise this effect the actual capacity would have to be increased, thus restoring things to the same condition. In other words, as the charging current is increased the maxima should move over into the region of larger capacities or shorter arc lengths, and this is the effect found experimentally.

To test the assumption that the sparking potential required to break down the insulation increased as the arc current was diminished a Braun cathode ray oscillograph was connected across the arc, so that the maximum deflection of the ray by the electromagnetic field measured the maximum instantaneous or sparking potential across the arc. Experiment verified this.

If horizontal sections are taken through the family of curves shown in Figs. 3 and 4 the variation of the current through the arc, as read by the direct-current ammeter, is found to have maximum and minimum values as the arc length is increased while the voltage across the arc is maintained constant. This is chiefly an effect due to the capacity of the arc, and is explained in the same way as the variation in voltage at constant current was explained, the two phenomena being complementary.

An alternative interpretation may be given to the curves if we assume that the voltage across the arc depends not merely upon the direct current through the arc, but rather upon the effective arc current, or the square root of the sum of the squares of the direct current and the oscillatory current. According to this interpretation, when the oscillations are at a minimum, corresponding to a critical value of the capacity of the arc, the effective current through the arc would be small, and the voltage across the arc would rise to a maximum even though the direct-current ammeter reading is kept constant.

Investigators who have used the ordinary spark-gap as a means of producing high-frequency oscillations have long been familiar with a similar phenomenon. For a given constant applied voltage at the high-tension transformer or induction coil there is a definite spark length which will give a maximum current in all the circuits. It is possible that this effect is due in part to the influence of the capacity of the spark, but it is probable that the variation of the sparking voltage and spark resistance with the spark length plays a much more important part than in the case of the short arc between large electrodes. A more marked effect has been observed by Duddell* in the secondary current of an induction coil when a mercury interrupter was used to make and break the primary current. It is probable that the resistance of the spark-gap in Duddell's experiment plays a relatively more important part than in the phenomena of the Lepel arc.

(To be continued.)

FLOUR MILL POWER SCHEMES.†

BY W. CRAMP, M.SC., AND B. E. STOTT.

In dealing with this question the authors first consider what proportion of the total cost of a sack of flour is to be placed to the account of power. For the purposes of comparison the following items are assumed as belonging to the power capital account: The cost of the actual power plant, and the cost of land and buildings should also properly be added, but the value of this item is so variable that when included it is specially mentioned. In other cases it is omitted.

The following combined rates of interest and depreciation are assumed: On buildings 7½ per cent., and on plant 12½ per cent. The following items make up the total cost of power: Interest and depreciation on capital outlay, cost of fuel and water, labour, oil waste stores, &c. When these items are all considered it will be found that the cost of power will vary from 2d. to 6d. per sack of flour produced, depending upon the size of mill, locality and other special conditions. The saving, therefore, to be effected by careful design and running of the power plant is quite sufficient to make it worth while to watch the costs in these days of keen competition.

Of the special conditions which affect the cost of power, that of site or locality is probably the most important. Given the site of a mill the cost of each sort of fuel immediately follows, and the output of the mill has then a direct bearing upon the choice of power plant. To cover these two items, "site" and "size," all flour mills are divided into three types: (1) Large port mills, (2) large inland mills (assumed to be near an industrial centre), and (3) small country mills.

Each system of drive has its own advantages, but it so happens that there is always some part of the plant which is better driven electrically than direct. For every complete flour mill plant consists of: (*a*) Intake plant and silo, (*b*) wheat cleaning plant, (*c*) mill proper, (*d*) warehouse. Between these the total power is generally divided in the following proportions: (*a*) and (*d*) 12 to 14 per cent., (*b*) 18 to 22 per cent., (*c*) 60 to 70 per cent. Not only is there this difference, but while (*c*) has an almost constant load, and runs 140 hours per week, and (*b*) and (*d*) are also nearly constant, and run

nearly always for the same hours, (*a*) is variable, and runs for a number of hours which depend upon the capacity of the building, the arrival of wheat and other conditions. Further, from insurance and other causes, (*b*) is always cut off from (*c*), while often (*a*) and sometimes (*d*) occupy entirely separate buildings. It thus happens that in almost all cases there is a portion of the plant which is more conveniently and economically driven by electricity. This is the more easily arranged since electric light is now the rule; and, therefore, it is only necessary to provide a larger generator and switchgear to deal with electric light and all plant that is situated at a distance, scattered as regards position or intermittent in operation.

A comparison of the schemes will make clear that the second can only be better than the first when the arrangement of the mill is such that the motor and generator losses are more than saved by improvements in the drives obtained. In the last case the boiler and generator and some of the cable losses are borne by the supply company; and when millers compare the price per unit at which they can generate with that offered by the supply company, this fact should be remembered. As a heat engine at low temperatures and pressures the turbine is more effective than the steam engine. A combination of the two, therefore, results in more power being developed per pound of steam, and if the load can be divided between turbine and engine in the proper proportions this is sometimes the best steam system.

With the exception of those items mentioned above, the power scheme may vary very considerably in its main features. There are, however, certain essentials which every such scheme must possess: (1) *Reliability.*—This point is regarded as of the very first importance. It is a *sine qua non* that the prime mover should be able to run for 140 hours per week with the minimum of attention. (2) *Regularity of Moment.*—It is essential that the speed and turning moment of the prime mover should be very regular. (3) If direct driving is to be adopted the speed of the prime mover should be such as will allow of rope drives on to the main shafts without the intervention of gears or countershafts, otherwise electrical transmission is necessary.

The authors next consider in some detail the various classes of steam plant that can be used, the advantages and disadvantages of each type being considered. Turbines are not adaptable to mill work owing to their high speed, and as regards running cost, there is little to choose between high and low-speed engines. A combined engine and turbine may often, too, be used with advantage. Gas engines, except those of the Diesel type, are not suitable for mill work.

In considering the question of electrical working the authors draw attention to the fact that if in many cases it is advantageous to transmit power electrically from steam, oil or gas, it will be much better to take power straight from convenient mains to any set of machines, and there utilise it by a motor direct connected to the line shaft. The absence of coal smoke or fumes, the small space required, the absolute regularity and ease of control, are points that should appeal to all millers; and when electricity can be obtained at a reasonable price per Board of Trade unit, doubtless it will attract the consumer. It is all a matter of disposition of plant and price per unit. In some respects flour mills are at a disadvantage as compared with other industries, since there is little or nothing to be gained by subdividing the drives of an ordinary flour mill; so little of the plant is intermittent in use, and the bulk of the machines must go as one unit. It would not pay, for instance, to drive the roller mills by independent motors, as the looms in the modern weaving shed are arranged, and the same applies to purifiers and centrifugals. On the other hand, the load factor of a flour mill is such as should tempt the most pampered supply company, since the main load is regular day and night, and by careful arrangement the auxiliary load can be put so as to avoid the central station peak. These points should not be lost sight of when millers are negotiating for a supply; nor should they forget that if the milling engineer is to get the best out of a site or ground he should be informed as to whether electrical driving is to be adopted before the buildings are even planned.

The best arrangements for a steam-driven mill are not necessarily best for one that has motors to its shafts, and there are, besides, differences in detail which must be allowed for. One of the chief of these is the speed of the line shafts. Certainly, if motors are to be used to their best advantage belts and ropes should be avoided as much as possible. This involves raising the speed of the roller mill shafts from 200 to about 350 revs. per min., and the centrifugal and purifier shafts may go even faster. All such auxiliaries as hoists, pumps, fans, &c., should be equipped with individual motors, and the machines themselves are usually most satisfactory if split up so that one or more motors take the roller mills, and other motors are arranged to take the purifiers, centrifugals, &c. There is no reason why, by proper electrical connections, the whole of the motors in the mill should not start at one time; and when the miller has his own generating plant, they may be arranged to start up all together in absolute synchronism with the engine.

As regards systems of generation, two are of importance—*i.e.*, continuous current and three-phase alternating current. Either may be used with success, but there is no question at all as to which is the better. Alternating current, besides giving steadier running and smaller speed variation with load, has great advantages from the point of view of insurance and capital cost, especially as regards transmission; while it is extremely flexible as regards pressure, and therefore very suitable where both lighting and power are required. It also lends itself particularly well to cases where a number of motors are to be started together.

Certain general conclusions are drawn from figures given in the Paper. Since electricity can rarely be supplied in large quantities (4,000,000 units per annum) at less than 0·3d. and in small quantities at less than 0·5d., it seldom enters as a competitor against steam, gas and oil. Turbo-electric drives are only of value for large mills, where, however, they stand pre-eminent. For country mills suction gas and oil are about equal, and when ground space and cleanliness are of importance the Diesel engine is to be preferred. For increasing the power and economy of existing plants the exhaust steam turbine is often of value; but it will not as a rule justify its inclusion in a new plant. Of electrical systems three-phase alternating current is to be preferred for all purposes—even where only part of the plant is driven electrically.

Suppose that at some port a number of millers were to combine their energies, and make use of one large power plant, what is the best that could be done in the cheapening of power? Suppose a case of three mills situated about 100 yds. each from the site of the central power station, and requiring altogether about 4,000 I.H.P. Steam turbines with electric drive could provide energy for about 2d. per sack in the case of a plant of 100 sacks' capacity, and since any decrease of this cost would, in the case of distribution to several mills, be more than compensated by cable losses, 2d. per sack may be taken as about the limit for the supposed case. Besides steam turbines there are only two economical ways of dealing with such a scheme: (1) Putting in Mond gas producers, leading the gas to boilers after passing through a recovery plant and burning it to produce steam which would drive the original steam engine. (2) Putting in Mond gas producers with recovery plant, leading the gas to gas engines with electric generators and distributing electrically.

If the mills are already equipped with up-to-date boilers and engines the first method would save a good deal of capital outlay and still show a small saving over individual steam plants. How much the saving would be it is impossible to say without knowing the exact conditions under which the plant worked. It is, however, safe to state that a capital outlay of £12,000 would be involved, and that the saving would only run to about ¼d. per sack. This arrangement, therefore, cannot be recommended, since it involves too many difficulties for too small a result. Of course, the above saving is nett after allowing for interest and depreciation on capital outlay. It may be stated that under such conditions the price of power per sack could not be less than 1·75d.

The second scheme would involve a greater expenditure, which, however, would be amply repaid, thus the power cost per sack produced would be, when ample margin is allowed for all eventualities, about 1⅛d., against 1¼d. by any other arrangement.

Earth Currents and the Telegraph.—A recent article in the "Elektrotechnische Zeitschrift" deals with this subject, and it is pointed out that when a single line is connected to earth at both ends it is traversed by a current not usually exceeding 1 milliamp., but this may rise considerably during magnetic storms. The following facts appear as the result of researches made on this question. Wires running north and south experience stronger currents than those running east and west; the currents are less the shorter the line; the currents undergo periodic variation, the daily and yearly fluctuations following those of the earth's magnetic field; and unusual fluctuations of the earth currents accompany unusual disturbances in the earth's magnetism. The customary earth currents do not interfere with telegraphy upon an earthed circuit, because even the most sensitive relay does not operate at such a low current. In times of severe disturbance, however, the interference may become very great, and even prevent the transmission of messages. In that case two earth-return circuits may be combined into a single unearthed circuit, or two telephone circuits may be combined to yield one telegraph circuit without interfering with its use for telephony.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free,
Canada	28s. 3d.	14s. 6d.	7s. 6d.	payable
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	in advance.

New volumes of "THE ELECTRICIAN" *commence in April and October.*

(This charge includes all the numerous Supplements.)

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

'THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1892. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 8s 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s; Europe, 2s; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the* 1911 *Edition sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription, 5s., post free.

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Now Ready.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d. *Now Ready.*

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming. M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms only, bound strong cloth. Price 5s. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gelpel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Balnes. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. [Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton. M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated. Prize 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (Lisbon Revision, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free. [Price 3s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. Being Vol. I. of a Complete Manual of Lifting and Hauling Machinery. *Ready shortly*, price 25s. nett.

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *Nearly ready.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *Nearly ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Hörner, by Justus Eck. *In Preparation.*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1878).

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON

(ONLY ADDRESS.)

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d

SPECIAL NOTICE FOR CORONATION WEEK.

"THE ELECTRICIAN" will be published on Saturday instead on Friday next week.

As it will be necessary for the Publisher to have the paper practical completed by Wednesday night (Friday being a holiday in London Contributors and Advertisers will please send their copy for Contributions and for new Advertisements and changes in runnin Advertisements not later than first post on Wednesday next week.

ELECTRIC TRACTION ON MAIN LINES.

The position of electric traction on main lines at th present time appears to be that, although some enginee are sceptical as to the value of electrical methods in su cases, electric traction on main lines is, nevertheles making steady progress. The New York, New Haven Hartford Railway affords a fitting example of this fa and a Paper by Mr. W. S. MURRAY, of which our readers w find an abstract on another page, is an important record the results obtained on this line. It is particularly gra fying to see the very great reliability of service that has be obtained under electrical conditions of working, the authc figures showing that the electric service is now more th twice as reliable as the steam service on the line. Apa however, from recording the satisfactory results obtain Mr. MURRAY preaches the gospel of standardisation. T creed being single-phase supply at 11,000 volts and a f quency of 25. As to the last-mentioned figure, engine in this country will not cavil at the frequency suggest as this has already been adopted with satisfactory resu though Continental engineers do not seem to be so unc mous in favour of this figure, and it is quite possible t the lower frequency of 15 periods may be favoured m

Digitized by Google

strongly. Nevertheless, a frequency of 25 has its advantages, and it is largely used.

With regard to the operating pressure, on the other hand, the position is not so clear. So far, in this country, a pressure of about 6,000 volts has been adopted for single-phase working, and therefore in all probability the tendency would be to favour this pressure unless good reason can be shown for something higher. It is certainly important that a uniform pressure should be adopted to facilitate the interchange of traffic, though this is more particularly so with suburban traffic than with main line traffic, because multiple unit equipment is likely to be used with the former whereas locomotives would find a place in the latter. It is not very feasible, however, to separate suburban from main line traffic. Probably a lower pressure than in America would be permissible, for the simple reason that there should not be any difficulty in arranging for the supply of energy in this country from large towns or from power companies along the route.

Finally, there is the question of the single-phase system being used for main line traffic. There certainly is much to be said in favour of this system for main lines, whatever may be the case on shorter lines, and Mr. MURRAY goes so far as to say that the first cost of the single-phase system is not more than 85 per cent. of its next best competitor, and its operating costs are less than this percentage.

There are one or two interesting points of detail to which Mr. MURRAY refers in the course of his Paper. One of these is in regard to the use of a subsidiary steel wire for the overhead transmission, this wire being used for the contact made by the collecting bows. In this way the copper wire can be reserved solely for the transmission of electric energy and is not subjected to any serious wear. So far, in this country, this form of construction does not seem to have been adopted. In the case of the South London branch of the London, Brighton & South Coast Railway, which is the only instance of a single-phase line in Great Britain on which there is a dense traffic, the usual copper wire is employed, and it has been found that the wear is extremely small. Theoretically, at least, it seems to be the right course to restrict the use of copper to the transmission part of the overhead construction and to use steel for supplying the contact, as the cost of renewal of the steel would be much less than that of copper. As to whether this would really be so in practice it is not so easy to say, as the additional steel wire must add something to the first cost, and if the wear is really very trifling it may not be worth while to incur this additional expenditure. It has sometimes been thought that a steel wire would not wear satisfactorily owing to corrosion, but no such difficulty seems to arise because the wire is always covered with a film of grease from the bows.

Another point on which Mr. MURRAY touches is the use of batteries for a traction system of this kind, and he gives his opinion emphatically against their use. It is well recognised that a battery enables the energy to be generated more cheaply under certain conditions by levelling up the load; and this increased cheapness may more than offset the loss due to the inefficiency of the battery. It is, however, purely a question of the character of the load, and Mr. MURRAY points out that if electric energy is used for handling freight traffic as well as passenger traffic the load can be so adjusted as to be very satisfactory from the station point of view. In this connection it is well to bear in mind that there is more than one class of locomotive used on a railway. The express locomotive is by no means inefficient, and it can be used fairly efficiently; but locomotives used for handling goods, and particularly those used for shunting, may be worked very inefficiently. Mr. MURRAY, in fact, as the result of tests, gives some very low figures and points out that the electric locomotive, when used for shunting, can be employed to advantage and may have a very high rating owing to the intermittent nature of the work. It seems not improbable that if electric traction on main lines is to justify itself, it will do so by embracing all classes of work and not by restricting itself merely to the handling of passenger traffic.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

The Principles of Electric Wave Telegraphy and Telephony. By J. A. FLEMING, M.A., D.Sc., F.R.S. 2nd edition. (London: (Longmans, Green & Co.) Pp. xviii. + 906. 28s. nett.

Prof. Fleming's well-known treatise remains in its second edition quite its former self in style and method, though it has increased some 50 per cent. in bulk. Just as when it was first published nearly five years ago, it forms a very comprehensive, up-to-date account of all the scientific aspects of wireless telegraphy, and it still deserves to be accorded the premier place as a book of reference on the principles of the subject. The additions and improvements found in this new edition are, of course, those due mainly to natural progress; but the opportunity has been frequently taken of correcting errors of omission and commission noticeable in the first edition. Among new matter may be mentioned a good account of recent measurements of dielectric strength, and of the absorption of electric waves by the materials of the surface of the earth, the latter especially being very fully treated. The recent theory and experiments, mainly due to German writers, on the resonance phenomena in coupled circuits is given great attention. The author, though describing just as fully as before the very bad method of measuring small mutual inductances between two coils (a method consisting in measuring the total self-inductance of the two coils in series and in opposition), now, fortunately, gives prominently a description of better methods and so removes a reproach that many people must have directed against the first edition. Among other new matter worthy of mention are the interesting results of Abraham's and of Love's calculations of the field round a Hertzian oscillator.

Looked at as a whole we conclude that this second edition is even more encyclopædic than the first. It is difficult to think of any paper or publication bearing directly on wireless telegraphy that is not referred to, and in a greater or less degree discussed, in this new big volume. Perhaps the chief faults of the work will, in time to come, be accounted to arise out of its author's desire to make it an all-embracing book of reference rather than a balanced expository treatise. This criticism is only strengthened by the fact that the index, though obviously laboriously and carefully compiled, is soon found to be but an imperfect guide to the contents of the volume. Finally, though the reader may close the book with the feeling that it is here and there a little out of touch with actual practice, he must admit that it is a marvellously rich store of the book-lore of the whole subject.

W. H. ECCLES.

Digitized by Google

Die Elektrische Fernübertragung von Bildern. By Dr. Robert Pohl. (Brunswick: F. Vieweg & Son.) Pp. viii. + 45. M.1.80.

Electricians who feel disposed to pay any attention to the telegraphy of photographs, writing, sketches, &c., will do well to study this little book, as it deals with most of the early systems and experiments of any importance, while treating in a later chapter of Prof. Korn's original method, which was the first to come into actual commercial use.

A considerable amount of space is devoted to the question of synchronising the transmitting and receiving apparatus, and, as a matter of fact, synchronism still remains the vital problem when working over long distances. In the Korn, Belin and Thorne-Baker systems, as at present arranged, the revolving drums of the apparatus make a revolution in two seconds, while the circumference of the drums is about 7 in. in each case. An error of a hundredth part of a second would thus distort the picture about a thirtieth of an inch—quite enough to deteriorate it seriously.

The most interesting process of telegraphing pictures is unquestionably that in which selenium is used to record the densities of different successive parts of a transparent photograph. Curves are given showing how Prof. Korn has overcome to a great extent the effects of inertia of the selenium cells, and his own method and Dr. Bidwell's are described in detail. On the other hand, the description of the telautographs of Bakewell and Korn can hardly be looked upon as satisfactory, as in the cursory description given of the latter it is impossible to deal with the extraordinary advance made by Prof. Korn with his Einthoven galvanometer method of reception.

THE PRINCIPLE OF THE STATIC BALANCER.

BY C. C. HAWKINS.

(*Concluded from p. 345.*)

Summary.—The theory of the static balancer is here developed on simple lines by the superposition of the component currents. An actual case is worked out numerically.

The simplest way of looking at the problem is to take the centre of the balancer as being earthed and, therefore, as remaining as a fixed datum at zero value. The third wire before

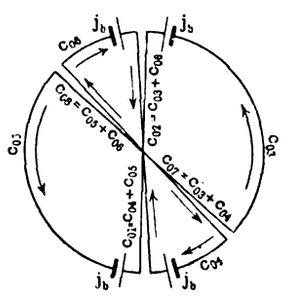

Fig. 6.—Out-of-balance Components in 2-Phase Case.

connection to the centre is at potential j_b, which may be positive or negative. We have only then to ask what currents c_{03}, c_{04}, c_{05}, c_{06}, superposed respectively on the four portions of the armature and each flowing *from* the point of low potential *to* the point of high potential, will lower or raise the potential of the middle *of the network* to zero. Each of the four portions of the armature will have its circuit completed by a share of the balancer and of the network resistances, so as to form four circuits which may be regarded as independent (Fig. 6). Thus, in R_2 there flows $c_{02}=c_{03}+c_{06}$ and in ρ_7 there flows $c_{07}=c_{03}+c_{04}$. Hence, to complete the circuit, *e.g.*, of c_{03}, we must take $R_2 \cdot \frac{c_{03}+c_{06}}{c_{03}}$, and $\rho \cdot \frac{c_{03}+c_{04}}{c_{03}}$.

The driving E.M.F.'s, which are represented by cells in Fig. 6 are in the two-phase case equal in each of the four circuits, *i.e.* $j_b = \frac{C_b}{2}(R_1 - R_2)$, or half the difference in the volts lost over the two sides of the network due to the direct current C_b; this E.M.F. is supplied by the armature induced E.M.F. in one portion and is, so to speak, saved in the adjacent portion, since the currents are in alternate directions in adjacent parts.

The coils being assumed to be wound on a common core, let $L = l + M$, where l is the leakage flux per unit current which is not linked with both coils and M is the flux due to unit current in one coil which also passes through the other coil, *i.e.*, their mutual inductance. The mutually induced E.M.F. in each coil is the same $= M\left(\frac{dc_{07}}{dt} - \frac{dc_{08}}{dt}\right)$, but in opposite directions relatively to the centre.

The principle is then shown by the four equations—

$$c_{03} \cdot 2R_a(1-q) + c_{02} \cdot R_2 + c_{07} \cdot \rho = j_b - L_3 \cdot \frac{dc_{03}}{dt} - l \cdot \frac{dc_{07}}{dt} - M\left(\frac{dc_{07}}{dt} - \frac{dc_{0}}{dt}\right.$$

$$c_{04} \cdot 2R_a \cdot q \quad + c_{01} \cdot R_1 + c_{07} \cdot \rho = j_b - L_4 \cdot \frac{dc_{04}}{dt} - l \cdot \frac{dc_{07}}{dt} - M\left(\frac{dc_{07}}{dt} - \frac{dc_{0}}{dt}\right.$$

$$c_{05} \cdot 2R_a(1-q) + c_{01} \cdot R_1 + c_{08} \cdot \rho = j_b - L_3 \cdot \frac{dc_{05}}{dt} - l \cdot \frac{dc_{08}}{dt} + M\left(\frac{dc_{07}}{dt} - \frac{dc_{0}}{dt}\right.$$

$$c_{06} \cdot 2R_a \cdot q \quad + c_{02} \cdot R_2 + c_{08} \cdot \rho = j_b - L_4 \cdot \frac{dc_{06}}{dt} - l \cdot \frac{dc_{08}}{dt} + M\left(\frac{dc_{07}}{dt} - \frac{dc}{dt}\right.$$

which would yield the numerical values of c_{03}, c_{04}, &c., and, as shown in Fig. 6, their directions are alternately clockwise and anti-clockwise.

Only one distribution of the instantaneous out-of-balance components can satisfy the conditions, and their numerical values continually alter as rotation proceeds and q changes from 0 to 1, when the process begins again. Strictly speaking, therefore, the E.M.F.'s self- and mutually-induced by the out-of-balance components would have also to be taken into account as shown above, but, being small, they may be neglected.

All the out-of-balance components are in general dissimilar, and when Fig. 6 is superposed on Fig. 3*c*, Fig. 7 is obtained, from which it follows that *all* the resultant armature currents are dissimilar so long as the tappings to the balancer and the brushes divide the armature into four portions.

The out-of-balance currents in each limb of the balancer are in the same direction relatively to the centre, *i.e.*, both outwards

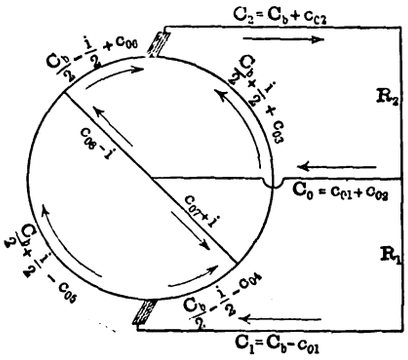

Fig. 7.—Final Distribution of Currents in System with 2-Phase Balancer.

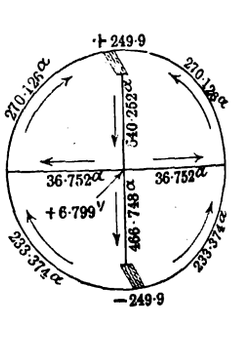

Fig. 8.—Numerical Value in Assumed Case.

or both inwards, and in Fig. 6 or 7 the outward direction is du to the fact that the positive side of the network has bee assumed to have the lesser resistance and therefore to be th more heavily loaded: if the negative side had been the mor heavily loaded, the components of Fig. 6 must be reverse The out-of-balance components in the limbs of the balance are also always dissimilar except when $q = \frac{1}{2}$.

The out-of-balance component in each section of the armatu is in the opposite direction to that of its adjacent neighbo (Fig. 6), but they are additive in each limb of the balancer an in each side of the network.

The total out-of-balance current is, therefore, numerically

$$C_0 = c_{01} + c_{02} = c_{03} + c_{04} + c_{05} + c_{06}.$$

The simple case of $q = \frac{1}{2}$ need alone be considered,* and ar E.M.F. self or mutually induced by the out-of-balance curren

* The grounds for this statement are given more fully in Jour I.E.E., *loc. cit.*, p. 714.

Digitized by Google

themselves may be neglected; under these circumstances the shares of the total out-of-balance current are,

$$\text{In } R_1, \qquad c_{01} = c_{04} + c_{05} = \frac{C_0}{2} \cdot \frac{2R_2 + R_a}{R_1 + R_2 + R_a},$$

$$\text{In } R_2 \qquad c_{02} = c_{03} + c_{06} = \frac{C_0}{2} \cdot \frac{2R_1 + R_a}{R_1 + R_2 + R_a}.$$

The total out-of-balance current is

$$C_0 = C_2 - C_1 = (R_1 - R_2) C_b \frac{W'}{U'} \quad . \quad . \quad . \quad . \quad (4)$$

and with $q = \frac{1}{2}$ in the two-phase case,

$$W' = (R_1 + R_2 + R_a) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

$$U' = 2R_1R_2 + \rho(R_1 + R_2 + R_a) + R_a(R_1 + R_2 + \tfrac{1}{2}R_a) \quad . \quad (6)$$

The numerical values* for the case of the 250 kw. dynamo above described, if we make $\rho = 0{\cdot}16$ ohm, will be (Fig. 8),

$q = \frac{1}{2}$.

E_a	$= 525$ volts
V_a	$= 500$,,
J_a	$= 25$,,
C_b	$= 500$ amperes
W'	$= 1{\cdot}05$
U'	$= 0{\cdot}71425$
C_0	$= 73{\cdot}504$ amperes
Out-of-balance current in R_1	$= 33{\cdot}252$,,
Out-of-balance current in R_2	$= 40{\cdot}252$,,
Out-of-balance current in each limb of balancer	$= 36{\cdot}752$,,
Additional loss of terminal voltage	$= 0{\cdot}175$ volts
Resultant terminal voltage	$= 499{\cdot}825$,,
Resultant divergence of centre potential, j_c	$= 6{\cdot}8$,,

The last figure shows how much the equality of the voltage on the two sides of the network has been improved as compared with the initial J_0, and this value for the new divergence remains to be proved.

The brushes which, before the connection of the third wire to the balancer, were at potentials of equal numerical value, but the one above and the other below zero, have their potentials changed as follows. Starting from the centre, which has been assumed as earthed, by the path o, b, d, the potential of brush d is positive, or above zero by the amount

$$-\left(\frac{C_0}{2} + i\right)\rho - L_1\frac{di}{dt} - l \cdot \frac{dc_{07}}{dt} - M\left(\frac{dc_{07}}{dt} - \frac{dc_{08}}{dt}\right)$$

$$+E_3 - L_3 \cdot \frac{di_3}{dt} - L_3 \cdot \frac{dc_{03}}{dt} - \left(\frac{C_b}{2} + \frac{i}{2} + c_{03}\right)R_a \quad . \quad (7)$$

and the potential of the brush f by the path o, a, f is negative or below zero, its value being

$$-\left(\frac{C_0}{2} - i\right)\rho + L_1\frac{di}{dt} - l \cdot \frac{dc_{08}}{dt} + M\left(\frac{dc_{07}}{dt} - \frac{dc_{08}}{dt}\right)$$

$$-E_3 + L_3\frac{di_3}{dt} - L_3\frac{dc_{05}}{dt} + \left(\frac{C_b}{2} + \frac{i}{2} - c_{05}\right)R_a \quad . \quad (8)$$

Their sum gives the arithmetical *difference* between the two new brush potentials, viz,

$$-C_0\rho - (c_3 + c_{05})R_a - l\left(\frac{dc_{07}}{dt} + \frac{dc_{08}}{dt}\right) - L_3\left(\frac{dc_{03}}{dt} + \frac{dc_{05}}{dt}\right).$$

At this instant L_3 may be assumed equal to L_1 and both $= L_a$, the inductance of one-half of the armature winding; it can then be shown that

$$c_3 + c_{05} = \frac{C_0}{2} - \tfrac{1}{2}L_a\left(\frac{dc_{03}}{dt} + \frac{dc_{05}}{dt} - \frac{dc_{01}}{dt} - \frac{dc_{06}}{dt}\right) \times \frac{1}{R_a}.$$

The above sum is, therefore,

$$= -C_0\left(\rho + \frac{R_a}{2}\right) - l\left(\frac{dc_{07}}{dt} + \frac{dc_{08}}{dt}\right)$$

$$-\tfrac{1}{2}L_a\left(\frac{dc_{03}}{dt} + \frac{dc_{05}}{dt} + \frac{dc_{01}}{dt} + \frac{dc_{06}}{dt}\right).$$

The two latter terms being in any case small and negligible, this reduces

$$-C_0\left(\rho + \frac{R_a}{2}\right).$$

If, therefore, half of this sum, but of opposite sign, is added to the potential of the centre, the potential of each brush is altered similarly and they become of equal numerical value but of opposite sign. The new potential of the centre is then the required divergence that has to be found, or

$$j_c = \frac{C_0}{2}\left(\rho + \frac{R_a}{2}\right),$$

and in general for n phases, when $q = \frac{1}{2}$ it is

$$j_c = \frac{C_0}{n}\left(\rho + \frac{R_a}{2}\right). \quad . \quad . \quad . \quad . \quad . \quad (9)$$

The new terminal voltage between the brushes is the difference between the potentials of (7) and (8), *i.e.*, when $q = \frac{1}{2}$,

$$d - f = 2\left(E_3 - L_3\frac{di_3}{dt} - L_1\frac{di}{dt}\right) - i(2\rho + R_a) - C_0 \cdot R_a - (c_{03} - c_{05}) \cdot R_a$$

$$- L_3\left(\frac{dc_{03}}{dt} - \frac{dc_{05}}{dt}\right) - 2M\left(\frac{dc_{07}}{dt} - \frac{dc_{08}}{dt}\right).$$

The E.M.F.'s self- and mutually-induced by the out-of-balance currents may again be neglected, and under this assumption, when $q = \frac{1}{2}$,

$$c_{03} - c_{05} = \frac{(R_1 - R_2)j_b}{U'}.$$

Further, at this moment,

$$i(2\rho + R_a) = E_3 - E_4 - L_3\frac{di_3}{dt} - L_1\frac{di_1}{dt} - 2L\frac{di}{dt}.$$

Therefore the new terminal voltage between the brushes is

$$v_{cc} = E_3 + E_4 - L_3\frac{di_3}{dt} + L_1\frac{di_1}{dt} - C_b \cdot R_a - j_b \cdot \frac{(R_1 - R_2)R_a}{U'},$$

or since $j_b = J_0$ when $q = \frac{1}{2}$,

$$v_{cc} = E_a - \left(L_3\frac{di_3}{dt} - L_1\frac{di_1}{dt}\right) - C_b \cdot R_a - J_0 \cdot \frac{(R_1 - R_2)R_a}{U'}. \quad (10)$$

As compared with equation (1) it will be seen that the last term is an entirely additional loss due to the presence of the out-of-balance current; the terminal voltage is lowered with an assumed constant E_a, but the amperes in R_2 are raised and the total output is improved. Thus, in our case of $q = \frac{1}{2}$, the additional loss of volts is $0{\cdot}175$, making $v_{cc} = 499{\cdot}825$, divided between R_1 and R_2 in the proportion of $256{\cdot}712 : 243{\cdot}113$. The total output is, therefore,

In R_1, $256{\cdot}712$ volts $\times$ $466{\cdot}75$ amperes $= 120$ kw.
In R_2, $243{\cdot}113$ volts $\times$ $540{\cdot}25$ amperes $= 131$ kw.

Total $= 251$ kw.

From what has been stated above, it follows that a division of the actual instantaneous currents c_3 and c_4 in the two limbs of the balancer into an alternating current i and an equal share of C_0, so that

$$c_3 = \frac{C_0}{2} + i$$

$$c_4 = \frac{C_0}{2} - i$$

is only true when the self-induced and mutually-induced E.M.F.'s are neglected and $q = \frac{1}{2}$. Yet with practical values for the quantities it is at other instants sufficiently near to the truth to make it a useful approximation. If a current through one limb of the balancer directed *outwards* from the centre junction is regarded as *positive*, while a current inwards towards the centre is regarded as negative, we can then say that the alternating-current component has its sign fixed in accordance with the time, and, as it flows through two limbs in series, is + in one and − in the other. The direct-current component is half the total out-of-balance current in a two-phase balancer, or, if there are n phases, is $\frac{C_0}{n}$, and in every limb has the same sign which is fixed once and for all according to which side of the network is the more heavily loaded; it is outwards and *positive* if j_c is *positive*, or $R_1 > R_2$, and the + side of the network is the more heavily loaded, while it is inwards and negative if the divergence of the centre potential from the mean is negative.

Since

$$C_0 = C_2 - C_1 = \frac{\frac{1}{2}v_{cc} - j_c}{R_2} - \frac{\frac{1}{2}v_{cc} + j_c}{R_1}, \quad . \quad . \quad . \quad (11)$$

$$\frac{v_{cc}}{2} \cdot \frac{R_1 - R_2}{R_1 + R_2} - C_0 \cdot \frac{R_1R_2}{R_1 + R_2} = j_c = \frac{C_0}{n}\left(\rho + \frac{R_a}{2}\right),$$

* The refinement in the following figures is necessary in order that the principle may be brought to the test of numerical calculation and the value of the out-of-balance voltage in each of the four circuits may be checked. The writer is well aware that in practice the data for R_a can only be very roughly guessed.

Digitized by Google

when $q=\frac{1}{2}$. Whence

$$C_0=\frac{v_{cc}}{2}\cdot\frac{R_1-R_2}{(R_1+R_2)\left(\frac{\rho}{n}+\frac{R_a}{2n}\right)+R_1R_2}. \quad . \quad . \quad (12)$$

and

$$j_c=\frac{v_{cc}}{2}\cdot\frac{(R_1-R_2)\left(\frac{\rho}{n}+\frac{R_a}{2n}\right)}{(R_1+R_2)\left(\frac{\rho}{n}+\frac{R_a}{2n}\right)+R_1R_2}, \quad . \quad . \quad (13)$$

where R_1 is the effective resistance of the network on the negative side, so that j_c is positive when R_1 is $>R_2$. The average *difference* between the terminal voltages on the two sides of the network is, of course, $2\,j_c$.

It must then be emphasised that the amount of the out-of-balance current or its percentage of the full-load current is not a function simply of the terminal voltage between the outers and the resistances of the network; it cannot be stated until the resistances of the balancer itself and of the armature are fixed. Further, so long as the balancer has any resistance, j_c can never disappear, and the degree of perfection of the balancing depends essentially upon the resistance of the balancer and armature.

From given values of R_1 and R_2 and of v_{cc}, it is only the maximum possible out-of-balance current with perfect balancing that can be stated, *i.e.*, the ideal when $j_c=0$ and the voltage on either side of the network is the same. This ideal value of C_0 is $\frac{v_{cc}}{2}\cdot\frac{R_1-R_2}{R_1R_2}$, whereas actually, from equations (12) and (13), we have

$$C_0=\frac{v_{cc}}{2}\cdot\frac{R_1-R_2}{R_1R_2}-j_c\cdot\frac{R_1+R_2}{R_1R_2}$$

$$=\frac{v_{cc}}{2}\cdot\frac{R_1-R_2}{R_1R_2}\left\{1-\frac{(R_1+R_2)\left(\frac{\rho}{n}+\frac{R_a}{2n}\right)}{(R_1+R_2)\left(\frac{\rho}{n}+\frac{R_a}{2n}\right)+R_1R_2}\right\}. \quad (14)$$

$$=\frac{v_{cc}}{2}\cdot\frac{R_1-R_2}{R_1R_2}(1-x). \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (15)$$

Here $(1-x)$ indicates by how much we fall short of the ideal, and the smaller the fraction x the better.

It is also evident that C_0 cannot be stated unless v_{cc} is known, and it has been shown that v_{cc} not only pulsates but is affected by j_c or C_0: hence, C_0 should be expressed in terms of an assumed constant E_{cc}. But if the excitation is raised when the balancer is connected so that v_{cc} is raised to equality with V_e when there is no balancer (and in practice V_e would be maintained at its required value across the outers), we have

$$\frac{j_c}{J_0}=\frac{(R_1+R_2)\left(\frac{\rho}{n}+\frac{R_a}{2n}\right)}{(R_1+R_2)\left(\frac{\rho}{n}+\frac{R_a}{2n}\right)+R_1R_2}, \quad . \quad . \quad . \quad (16)$$

$$=x,$$

so that x is then also the fraction which the new divergence is of the initial without any balancer for the same value of the terminal voltage at the brushes.

The complete impracticability of a non-inductive balancer is evident from a short consideration. The effective value of the alternating voltage impressed upon the balancer depends upon the wave-shape and so upon the ratio of the polar arc to the pole-pitch, just as in a rotary converter. Assuming provisionally a sinusoidal wave, the effective voltage applied to one phase of the balancer (*i.e.*, to one of the coils, not between the slip-rings) is $\frac{V_e}{2\sqrt{2}}$, whatever the number of phases; if, therefore, the balancer were a simple ohmic resistance without inductance, the effective value of the natural alternating current in any phase would be $\frac{V_e}{2\sqrt{2}\,.\,\rho}$, and its maximum value $\frac{V_e}{2\rho}$. The ratio of this to the share of the total out-of-balance current which the phase carries would be

$$\frac{I_{max.}}{C_0/n}=\frac{\frac{V_e}{2}\cdot\frac{1}{\rho}}{\frac{V_e}{2}\cdot\frac{(R_1-R_2)(1-x)}{nR_1R_2}}=\frac{n}{\rho}\cdot\frac{R_1R_2}{(R_1-R_2)(1-x)}.$$

Since the moment of maximum alternating current would, with a non-inductive balancer, coincide with passage of the phase past the brushes, the armature resistance term in equation (16) vanishes, so that

$$x=\frac{(R_1+R_2)\frac{\rho}{n}}{(R_1+R_2)\frac{\rho}{n}+R_1R_2},$$

and the ratio finally becomes

$$\frac{I_{max.}}{C_0/n}=\frac{R_1+R_2}{(R_1-R_2)x}. \quad . \quad . \quad . \quad . \quad . \quad (17)$$

It thence follows that so long as the balancer is non-inductive, $I_{max.}$ must necessarily be larger than C_0/n, or the actual current in each limb must at least, for a part of a revolution, have its direction reversed, as shown in Fig. 9, and this is always the case on light loads, when C_0/n is less than $I_{max.}$

The curve of current in either limb is therefore alternating, but with the waves symmetrical not about the zero axis but about a horizontal axis at a height equal to C_0/n.

The average alternating watts of the phases are then $n\cdot\frac{V_e^2}{8\rho}$ and $\frac{n}{\rho}\cdot\frac{(R_1+R_2)(1-x)}{xR_1R_2}$. When the generator is well loaded, the useful output is not far different from $\frac{V_e^2}{R_1+R_2}$, even if the load is unbalanced, so that the ratio $\frac{\text{alternating watts in balancer}}{\text{output in network}}$ becomes approximately $=\frac{(R_1+R_2)^2}{8R_1R_2}\cdot\frac{1-x}{x}$, and if we assume $R_1=1\frac{1}{2}R_2$, it is $=\frac{1}{2}\cdot\frac{1-x}{x}$. If, therefore, $x=0{\cdot}25$, the alternating watts would be $1\frac{1}{2}$ times the useful output, from which the impracticability of the non-inductive balancer is evident.

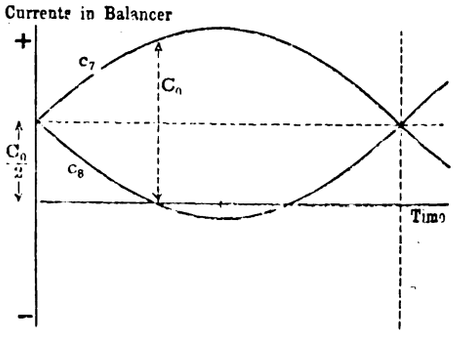

FIG. 9.

A very low ohmic resistance, such as will make the potent difference of the two sides of the network nearly equal, m therefore be combined with a counter E.M.F. to check t excessive waste of power and inefficiency of a simple resistar when the slip-ring tappings draw near to and pass under t brushes at the epoch of maximum impressed potential differen This is secured by making each limb highly inductive, so tl the natural alternating current is limited rather by the actance $2\pi fL$ than by the resistance. Its effective value n becomes $\frac{V_e}{2\sqrt{2}\sqrt{\rho^2+4\pi^2f^2L^2}}$ where L = the inductance of phase, and by making L large enough we become practic independent of ρ, and the ratio of $I_{max.}$ to C_0/n can be inc nitely reduced. One effect, as has already been mentione to alter the moments of time when the alternating curren each phase passes through zero or a maximum, but more portant is the lesser amplitude of the alternations or pu tions in the current. If the several phases or limbs are wo on entirely separate cores and have no common magn circuit, then, as L is increased, the time during which the is actually reversed becomes gradually reduced, until, f certain value of L, the flux is never reversed, but simply va from $B_{max.}$ to zero. With a still further increase of L, the varies from a maximum to a minimum, but always remain the same direction, so that we have, in effect, a constant n

Digitized by Google

netic flux upon which is superposed an alternating flux. The greater the amount of the inductive action, the flatter becomes the curve of instantaneous current, until in the ideal case of a very high inductance, the core of each phase will carry approximately a constant flux corresponding to half of the out-of-balance current.

When the limbs are entirely separate magnetically, $\frac{C_0}{2}$ would tend to impart to the cores an initial and permanent magnetisation upon which would be superposed an alternating magnetisation; the result would be an unequal change of flux in the two limbs for the same variation of the current on either side of the mean, *i.e.*, an unsymmetrical hysteresis loop, and the simultaneous values of dB/dH in the two limbs, or, which is the same, of L_7 and L_8, would not be the same at each instant. In this case the normal division of the total out-of-balance current between the phases at any instant is altered, and adjusts itself automatically to the changing conditions, or it may be said that the imaginary division of the current in each limb into its alternating and direct-current component is no longer so true a representation of the facts. But as soon as the two limbs of the balancer are wound over a common core, if the direct-current out-of-balance components could be arranged to magnetise this common core in opposite directions, they would cause no resultant initial flux, and the alternating flux would alone remain. This can always be secured without any difficulty so long as the balancer has an even number of limbs, 2, 4, 6, &c., which can be arranged in pairs, and this has, in fact, been shown in Fig. 1, where the out-of-balance components either both outwards from or both inwards to the centre will neutralise one another magnetically. We then return to a magnetisation varying between equal positive and negative maxima of flux, giving a symmetrical hysteresis loop and equal instantaneous values of L_7 and $L_8 = L$, as originally assumed. The difference in the ampere-turns of the two limbs is now the magnetising force, and the rise and fall of this difference simply reproduces the natural alternating current which magnetises the common core and supplies the requisite counter E.M.F.

To design the static balancer it is then only necessary to remember that the winding of each of the n phases must carry $\frac{1}{n}$ of the total out-of-balance current *plus* the natural alternating current, which would arise if the effective voltage $\frac{V_e}{2\sqrt{2}}$ were applied to the phase.

The problem of design usually presents itself as follows. It is, with given resistances of the network, by what percentage may the voltage on one side be permitted to exceed the true mean voltage? If not given, the resistances of the network must be approximated. Let y = the fraction which the excess voltage on one side may be permitted to be of the true mean, $\frac{V_e}{2\sqrt{2}}$. Then from equation (13) the resistance ρ of each phase of the balancer *must* be such that

$$\frac{\rho}{n} = \frac{yR_1R_2}{R_1 - R_2 - y(R_1 + R_2)} - \frac{R_a}{2n}, \quad . \quad . \quad . \quad (18)$$

$$\rho = \frac{y \,.\, n \,.\, R_1R_2}{R_1 - R_2 - y(R_1 + R_2)} - \frac{R_a}{2}. \quad . \quad . \quad . \quad (19)$$

The value of C_0 with the shunt circuit included can also be given in simple terms when $q = \frac{1}{2}$. Without any balancer

$$C_a = \frac{E_a}{\dfrac{(R_1 + R_2)R_s}{R_1 + R_2 + R_s} + R_a}, \quad . \quad . \quad . \quad . \quad . \quad (20)$$

where R_s is the resistance of the shunt, and the current through the network is $C_b = C_a - c_s$, where c_s is the shunt current. The full expression for W' is then the denominator of (13) instead of simply $R_1 + R_2 + R_a$, and

$$C_0 = \frac{(R_1 - R_2)(C_a - c_s)\left\{\dfrac{(R_1 + R_2)R_s}{R_1 + R_2 + R_s} + R_a\right\}}{2R_1R_2 + \rho(R_1 + R_2 + R_a) + R_a(R_1 + R_2 + \frac{1}{2}R_a)}. \quad . \quad (21)$$

The inaccuracy in the denominator of C_0, due to the addition of the shunt circuit, is negligible, and allowances can be made for the resistance of the series magnet winding in the values assumed for R_1 and R_2.*

In the two-phase case one winding is placed on each limb of the closed magnetic circuit, or, preferably, half of each phase is wound on each limb, as in Fig. 10. In the four-phase case, either two separate two-phase choking coils may be employed, or, better, the two magnetic circuits have a common yoke, the section of which is approximately $\sqrt{2}$ times the section of either core (Fig. 11); in each pair of phases the coils may be wound one over the other or intermixed. The six-phase case requires a three-legged choking coil either as in Fig. 11, but with limbs of equal section, or with three limbs at the corners of a equilateral triangle, united top and bottom by three-armed stampings.

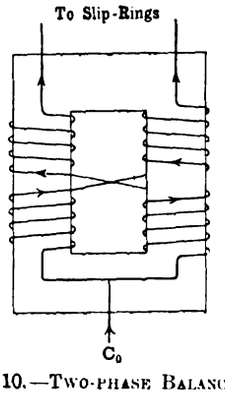

FIG. 10.—TWO-PHASE BALANCER.

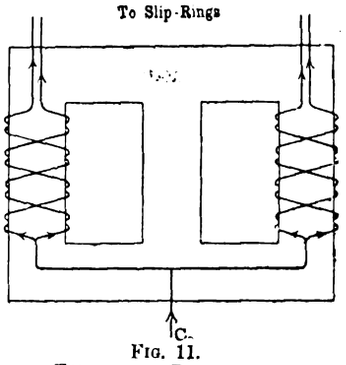

FIG. 11.
FOUR-PHASE BALANCER.

In all cases the advantage of increasing the number of phases is to distribute the out-of-balance current more uniformly over the armature winding and so to lessen the power wasted and reduce the local heating near the armature tappings just as in a rotary converter. It is not, however, worth while to go beyond six phases.

The three-phase arrangement stands quite by itself, inasmuch as it is not possible to annul the constant flux unless the middle wire connection is itself wound round each of the three cores to the amount of one-third of the number of turns on each limb of the balancer winding proper, *i.e.*, sufficient to counteract the direct-current ampere-turns of the three phases (Fig. 12). Unless this device, due to Prof. Steinmetz, is adopted, the cycle of flux-density in the iron core is carried out fairly high up on the curve of magnetisation, and, in consequence, the hysteresis loop and the hysteresis loss is greater. The extra expense of adding a fourth slip-ring is, therefore, usually warranted by the greater economy in working.

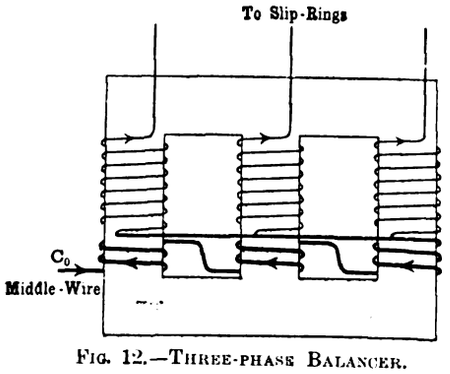

FIG. 12.—THREE-PHASE BALANCER.

An objection to the use of static balancers may finally be mentioned; it is that difficulty may arise when they are used with two or more dynamos working in parallel, unless the out-of-balance current is fairly small as compared with the current of the smallest generator. It is, therefore, best adapted to the case of a single generator in a large installation, *e.g.*, of a factory which uses appliances of low and of high voltage.

* In the three-phase case the denominator of equation (21) becomes

$$2R_1R_2 + \frac{2}{3}\rho(R_1 + R_2 + R_a) + \frac{2}{3}R_a(R_1 + R_2 + \frac{1}{6}.R_a),$$

and in the four-phase case,

$$2R_1R_2 + \frac{\rho}{2}(R_1 + R_2 + R_a) + \frac{R_a}{2}\left(R_1 + R_2 + \frac{R_a}{4}\right).$$

CORRESPONDENCE.

THE NOMENCLATURE OF PRIMARY AND SECONDARY SOURCES OF LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: If practical units in any branch of engineering are found to differ from scientific units, it need not be assumed that there is any conflict or confusion. The measurements of pressure as a head of water in feet, or as a pressure per square inch, or in atmospheres, or even as millimetres of mercury, are all unscientific. The scientific unit is the dyne per square centimetre, and the International Physical Congress at Paris in 1900 recommended that it should be called a *barie*. Somebody else called it a *barad*, and the *megabarie* was so inviting to others that nothing was done. Meanwhile the dyne per square centimetre is modestly waiting outside the engineer's office (gossiping no doubt with a poundal), until the dyne has got taken on. We still graduate our steam gauges in pounds per square inch.

There are two primary physical quantities in photometry—the one, luminous intensity, commonly called candle-power, and the other luminous flux, the unit of which is the lumen. From a point source of I candles there is a luminous flux of $4\pi I$ lumens. One candle-power is therefore the luminous flux per steradian or unit solid angle. The secondary quantity called illumination may be defined as the illumination produced by 1 c.p. at a distance of 1 ft. on a surface facing the light, or by the lumens per square centimetre. I do not, as Mr. Murphy suggests, object to the latter mode of defining illumination, but the question is, Which is the most convenient method for engineers and borough surveyors? I agree with Mr. Murphy that the rating of a projector lamp in candle-power is generally meaningless.

In electric and magnetic units, 4π is sometimes discovered in unlikely and apparently useless places. Attempts have been made to put it in a convenient place by so-called rational systems of units. Oliver Heaviside proposed that a unit magnetic pole should be defined as the pole from which unit magnetic flux proceeds. A pole thus defined would have a strength of m units if it attracts or repels another equal pole placed at a distance d centimetres, with a force of $m^2/4\pi d^2$ dynes. The Heaviside units would all be incommensurable with our practical units. Giorgi made the ingenious proposal to eradicate 4π from the units of current magnetic flux, &c., and to plant it in the permeability or dielectric constant of ether or air where it would trouble nobody.

Mr. Murphy asks whether I would prefer to measure the density of a magnetic field in terms of feet and unit poles. Setting aside the fact that I should probably turn my rule over and use millimetres, if the measurement were feasible, I find myself debarred for the simple reason given by him, "unit poles or unit charges do not exist." Why he prefixes this statement by "fortunately for the practical engineer," is not clear. But the analogy must not be pushed too far. The trouble about magnetic poles is that the lines of force from them seldom radiate from a point in straight lines. An advantage in optics is that the radiation is in straight lines, and except in unusual circumstances, the source may be regarded as a point. In other words, the law of inverse squares applies, and when Nature is so obliging as to work to this law, engineers are generally glad to take advantage of it. In optics we may use 4π or drop it, whichever is most convenient, without affecting our units.

I have pointed out elsewhere in connection with this question that there are three ways of measuring rainfall: First, tons per acre or cubic feet per square foot—that is, three dimensions of water and two of land; second, square feet per lineal foot, as in gauging the section of a river, two dimensions of water and one of land; or, as rainfall is commonly described, inches on or at a point, one dimension of water and none of land. All three are convenient. According to the reasoning of Mr. Murphy, Mr. Carl Hering and others, the last method is an anomaly. Though the schoolmen calculated how many angels could dance on the point of a needle, no quantity of water can rest on a point. The expression of rainfall in inches is an economy of dimensions derived from measurements made with a rain-gauge. In general, an engineer does well in avoiding quantities with redundant dimensions, though at his leisure he may reflect that some have been suppressed.

The projected area of a candle-flame in a horizontal direction is about 0·4 sq. in. Since it emits 1 c.p. the specific brilliance of the flame may surely be described as 2·5 c.p. per square inch. Mr. Murphy says that "if the light source has area it cannot (except by a conventional licence) be measured in candle-power." Does this conventional licence refer to the fact that it is not a point source? This is the sort of question which often confronts an engineer. He has to determine the error involved and consider whether he is justified in neglecting it. It can be shown that at a distance of 9 in. the light from a candle-flame is about 1 per cent. smaller than from a point source. That is less than the error of observation with such a source, and 9 in. is a smaller distance than is generally used on a photometer. At 6 in. the difference would be about 2 per cent.

While in various theoretical considerations, the conception of luminous flux is a necessity and 4π must put in an appearance, I maintain that for other purposes there is nothing unscientific or illogical in using candle-power as the unit of luminous intensity, candle-power per square inch or per square millimetre as the unit of intrinsic brilliance, and the foot-candle as the unit of illumination. Two letters by Mr. Roger T. Smith in recent numbers of the "Railway Gazette" show that illumination is often a more important quantity than candle-power for the practical engineer.—I am, &c.,

Westminster, June 13. A. P. TROTTER.

IMPENETRABLE TARIFFS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have before me the copy of a speech made a few days ago by the chairman of a large electrical engineering company on the occasion of their annual meeting of shareholders. Amongst other things it contains the following statement: "It must also be remembered that in this market of free imports we have to meet the competition of most powerful continental manufacturers, who with their home markets secured to them by *impenetrable tariffs* are able to work at a good profit," &c. By "powerful continental manufacturers" I suppose the speaker means, principally, German manufacturers. If so, I cannot understand how such a statement passed unnoticed and without protest from those present at the meeting, some of whom must surely know that the German tariff is anything but impenetrable, at least as far as it applies to electrical material. The import duties levied in Germany on electrical goods of English origin work out at about 2 to 4½ per cent. of the value for motors, ¾ to 1½ per cent. of the value for glow lamps, 3 to 4 per cent. of the value for turbo-generators, whilst lead-covered cable and a few other classes of goods pay no import duty at all.—I am, &c.,

London, June 10. C. PFEFFER, General Manager A.E.G. Electric Co. (Ltd.).

A QUESTION OF IDENTITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A post card signed "J.S.", recommending the recipient to read some article in a periodical, has been widely circulated; and those of my professional friends I have met since have asked me about it. May I use your journal to tell those I have not met that I am not the "J.S." who wrote the post card? I never recommended anybody to read anything.—I am, &c., J. SWINBURNE.

Westminster, June 15.

Electricity Supply in Italy.—According to the "Elektrotechnik und Maschinenbau," there were last year 250 gas works and 7,127 electricity supply stations in Italy; 5,148 of the latter only supplied private plants. The total gas consumption was 8,180 million cubic ft., and the total electricity consumption 113 million kw.-hours. The electricity consumption increased 18 per cent. over that of the previous year.

TROUBLES ON OVERHEAD POWER LINES.*

BY C. W. R. CAMPBELL.

In the first instance, the geographical direction of the line has a decided influence on the effect of atmospheric disturbances, so far as I have observed in this country; here it is, I think, common experience that the most troublesome lines are those running north and south, or in wave form over high and low ground. This, unfortunately, is beyond our control commercially.

As to the spacing of the conductors on the towers. It is acknowledged, I think, that the correct arrangement of conductors is that of the apex of the triangle on top; and I think that where overhead earth wires are used, it would always be better to carry the top cross-arm out, so that the outside earth wire would be at least 18 in. in front of the outside conductor if any sag or breakage took place. This would enable the line to be kept in commission until a repair could be effected; and I have an idea that from the protective point of view this arrangement might be better.

With insulators the chief troubles experienced beyond faulty material (which is rare nowadays) have been through flashing-over caused by lightning, or by birds, and I fancy the bird trouble is the greater. I say this because of the numerous instances in which birds are found at the foot of the pole in question, with signs of burns. With regard to flashing-over caused by surges and lightning, it appears that little damage is usually caused by the actual flash-over, but the ground insulator is nearly always caused by the arc following the flash-over.

With regard to the lines formerly in use, erected on shorter poles, a good deal of trouble used to be caused by objects being either thrown over the lines and guard wires, or maliciously thrown over. A source of trouble during high winds, which is not, by the way, confined to lines with short poles, is from long strips of gum-tree bark and branches. These are often carried quite long distances. The fire trouble has sometimes been very serious in certain districts, particularly so since the wire does not easily fuse and clear itself. Main transmission tower lines are not very subject to these troubles, being so much higher.

With reference to lines coming down through breakage due to fusing (material (which is rare), or burning through broken insulators, point of interest is the method of binding the conductors on the insulator. From the repair-gang's point of view, and I also think from the point of view of cost, the ordinary binding wire is perhaps preferable to any form of clamp. In any case, the line has to be patrolled and repaired, but if clamps are used on long spans the strain at the moment of breaking is bound to bend over a certain number of insulator pins, which would have to be replaced; whilst with binding the copper slips through and saves the pins. Turning to the long-span construction with suspension type insulators for dead-ending at corners and certain definite distances and pin-type insulators, several breakages of the suspension type have occurred. It is usually very difficult to diagnose the trouble; in only one instance have we found an undoubted case of puncture. In some cases, I believe, owing to the straps not bedding properly on the insulator, any extra strain during very high wind cracking the porcelain and the shock breaking through the other insulators in series. In several instances—in fact, in most—it has been possible, after the trip caused by the breakage, to continue to keep the line in service by the shackles on the other side of the tower supporting the conductor. It has been suggested that the loop between the two insulator shackles should be carried on a pin-type insulator above the cross-arm instead of below, as is customary. I think, however, that, apart from the additional cost, the chance of being able to keep a line in service until a convenient time for repair is greater with the loop below the cross-arm. The reason for the conductor itself generally breaking up is that the burning is confined to the U pieces of the suspension insulators, which clear themselves. When a line runs through a dip, trouble is sometimes caused by the line having been pulled up too tightly during the hot season. On the first frost it contracts and pulls away from the binders, in some cases coming in contact with the cross-arm above.

With regard to pole lines in soft ground, great care has to be observed in avoiding chances of wash-outs during heavy rains. Also in such cases it is essential to put plenty of wind-stays. In any long stretch of straight line where poles are used, it is preferable to stay every fifth pole on all four corners to avoid the trouble spreading in case of line-breakage. With regard to the staying of poles, an interesting source of trouble is a cow or mule rubbing itself against the stay and setting the conductors and earth wires swinging. Barbed wire is recommended by some to prevent this, but fencing round the chief danger points seems to be the only remedy.

Trouble has frequently occurred through the guy-rods not having been set in a direct line with the pull. The safest plan is to undercut the hole for the plate, and cut a slot in the ground for the rod; this disturbs the ground very little, and the guy needs little attention after.

Outside links should, of course, be avoided when possible; but seeing that they are frequently unavoidable, a few notes may be of interest. The jumpers from the main line to the branch line links are sometimes connected straight on to the metal carrying the link contacts. This is bound in time to cause trouble if the links are on a separate pole, owing to the constant movement gradually loosening the links. The jumpers should invariably be carried to a separate insulator on the link pole, and then connected by a lead as flexible as possible to the link contacts. The older type of links were usually carried on the top of pin-type insulators; these were very inconvenient to handle, and the suspended type should always be used. It is important to carry all wiring to the links on the top of the frame, so as to allow the space below them to be absolutely clear for operating safely.

* Abstract of a Paper read before the South African Institute of Electrical Engineers.

DISCUSSION.

Mr. BERNARD PRICE thought it was always necessary in overhead work to have some means of curing the trouble after it had taken place, as well as endeavouring to design lines so as to prevent it. If they had a long transmission line, such as was now in use in that district, they must, in considering the effect of lightning, distinguish between two possible effects—the local effect on the line, and the effect on the sub-stations and the stations at the end of the line. The local effect was extremely difficult to avoid entirely. The earth wires over the lines were probably of some advantage, but it was still very difficult to prevent damage to insulators, especially in severe storms. It might be possible, by increasing the size of the insulators, to prevent almost entirely, if not entirely, the induced effect from a neighbouring flash, but it seemed impossible to safeguard against a direct flash on the lines, for that must cause damage to the insulators. The metallic ring around the insulators was said in America to go a long way towards safeguarding the insulators. It had not been tried here, and it would be a matter of considerable difficulty and expense. It was very unusual to find two lines damaged in the same storm on the same route, so if one arranged the network by running the lines feeding a given section or district by different routes, in a given storm no two lines at one point would be affected. Thus, local effects on the lines need not cause a stoppage of supply unless the automatic tripping gear on switches should fail, or the effect was transmitted to apparatus in the sub-stations or stations at the end of the line. His experience was that they were still very far from having an entirely satisfactory safety valve for high frequency effects at stations. There was also the question as to whether overhead line troubles would not be very much reduced when higher pressures were used. In the course of 12 months they would be running lines at 80,000 volts in that district, and judging from the published experience of companies operating at 100,000 volts, many of the present troubles might be expected to disappear. He believed that in the region of 100,000 volts they were reaching a point where the insulation provided for the lines approached that necessary to deal with the high frequency overhead effects that took place at times of lightning discharge.

Mr. A. E. GIBBS noticed that the author had omitted all mention of one cause of trouble with overhead power lines, namely, pilot cables. The birds brought the sportsman with his gun, and trouble followed. Often the shot only just penetrated the lead sheath, and the trouble did not show itself till the next rain-storm. A point of interest in a long overhead power line was that, while still dead and free at either end, quite a heavy shock could be received from it. When building a long line it was necessary to earth it at frequent intervals. The charge was not due to a lightning storm, but would be there on an absolutely fine day, more especially if there was a high wind. On a fine, dry, windy day one could get a big shock from the lines.

Mr. G. A. WEBB corroborated the point mentioned by Mr. Gibbs, and said he found that he could obtain a much heavier discharge from the lines when there was a very intense sun. He once had trouble with some guard wires owing to expansion and contraction, resulting in breakages; he got over the difficulty by using eye bolts about 2 ft. 6 in. long, and placing spiral springs of suitable dimensions between a back plate and the cross-arm. This arrangement answered perfectly. Some such method must be beneficial to the conductor, as when contraction took place (provided the springs were suitably proportioned to the length of line) there would be no elongation of the conductor, the contraction being taken up by the springs.

Mr. G. NOWLAN thought it possible to protect a line by having a non-inductive resistance always on the line. In regard to the binders, the breaking of power lines was not always caused through the binders being too tight, or the wind, but it was caused by an electrical effect, because at high voltage a long stretch of wire not supported would get up a movement depending on the frequency.

Mr. G. T. PLUMB believed that after extensive experiments in Canada it was found that 75,000 volts gave the highest commercial efficiency, and he thought that arresters gave more trouble than the inductive effects.

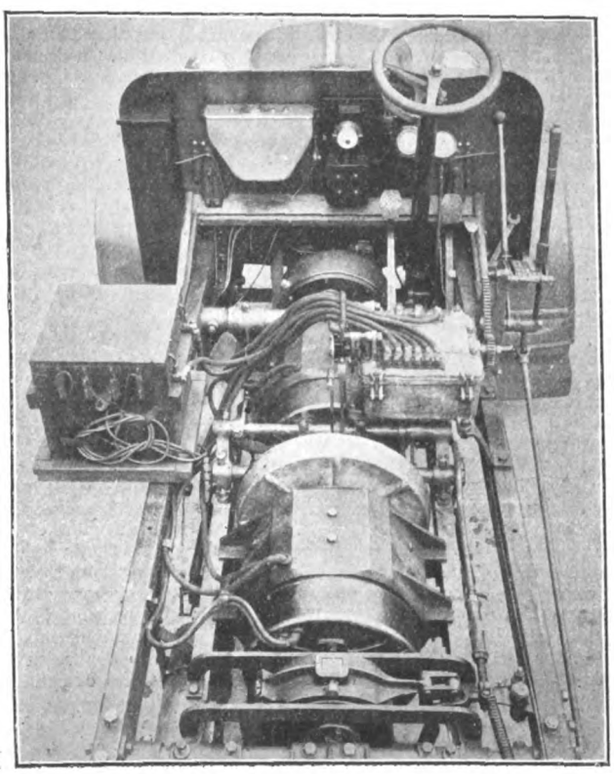
THE "THOMAS" ELECTROMECHANICAL TRANSMISSION.

In our issue of May 5th we described an electromechanical transmission system of a distinctly novel and interesting character which was installed on a 30–40 H.P. lorry. This vehicle was at that time under test by the Royal Automobile Club, a 2,000 miles' trial having been arranged over an exceptionally hilly route in Kent. We have now received a copy of the report which has been made by the club, and which shows that the vehicle came out of the tests with credit.

The illustration herewith is a top view of the transmission gear on the lorry after the R.A.C. trial. The battery seen at the left-hand side of the photograph is used for car lighting and also for starting the engine. The controller with its leads will be noticed at the right-hand side of the car.

The total weight of lorry fitted with the "Thomas" transmission was 4·5 tons; and a permanent load (sand) of 3 tons was carried, which with passengers brought the average running weight of the vehicle to 7·68 tons. Although the speed was not



Top View of Lorry after R.A.C. Trials.

allowed to exceed 12 miles per hour, the average speed worked out at 10·47 miles per hour. On a level route this speed limit would not have affected the fuel consumption, but on a hilly route such as that chosen it was a serious handicap, since it meant that it was impossible to rush any of the hills and so make use of the kinetic energy of the moving vehicle.

The report mentions that during the trial no work was done upon the transmission, except lubrication, 5½ oz. of oil being used for this purpose. The total water consumption throughout the trial was 20 gallons, or one gallon per 100 miles, whilst 265·8 gallons of fuel were used, equivalent to 7·55 miles, or 58 ton-miles, per gallon. There is no doubt that during the trials the continual strain and anxiety of the test affected the drivers to some extent, so that they could not drive as efficiently as at the commencement. A preliminary trial run over the route showed a fuel consumption equivalent to 9 miles per gallon. It should be noted that the above figure of 7·55 miles per gallon includes the charging of the battery for engine starting and car lighting.

Up Riverhill, which is ¾ mile long, the greater part of the gradient being 1 in 9·4, 1 in 10·1, 1 in 11·2 and 1 in 12·3, the fastest average speed was 7·2 miles per hour, the average of all ascents being 6·65 miles per hour. The average rise of temperature of the casings of the electrical machines after ascending the hill was 22·8°C.

The report concludes as follows:—

Condition after Trial.—The transmission was dismantled after the trial. The condition throughout (with the following specified exceptions) was found to be very good. The teeth of the double-helical planetary wheels were found to be somewhat worn. In the controller box two brushes, four sparking tips and a brush contact block were found sufficiently burned to require replacing. This was done by one man in 7 min. 57 sec.

It may be noted, however, that the planetary gear wheels had been used for 2,000 miles before the official trial commenced.

HOLBORN STREET LIGHTING.

At the meeting of the Holborn (London) Council on Wednesday the question of the improved lighting of the borough came up for consideration on reports from the whole Council sitting in Committee and from the Finance Committee.

It will be remembered that, as a result of a recommendation last year by the Works Committee in favour of the gas company's tender (£7,527) being accepted as against a tender by the electric light company at £6,602, the report was sent back, with instructions to obtain fresh tenders on a definite specification to be prepared by the borough surveyor. The gas and electric light companies then submitted a joint tender for the lighting of the borough partly by gas and partly by electric light, the disclosure of the various companies' figures for the previous tenders having made this (as the companies contended) imperative. This joint tender was then referred to the whole Council for consideration. The report now submitted that they had considered the tender of the Gas Light & Coke Co. and the Metropolitan Electric Supply Co. for the public lighting of the borough and which provided for an entire re-arrangement of the present system of lighting so that approximately one-half of the borough would be lighted by gas and the remainder by electricity. The companies undertook for £6,950 per annum to install and maintain suitable lamps and fittings and to supply electric current or gas as necessary for giving a minimum of 425,140 c.p. There would be 20 electric arc lamps of 1,800 c.p. in High Holborn, New Oxford-street, and Kingsway, 13 electric lamps of 600 c.p. in High Holborn and New Oxford-street, two 400 c.p. electric lamps in Brooke's Market and in Chancery-lane, 54 in Gray's Inn-road, 42 in Theobald's-road, four in Holborn-circus, 22 in Farringdon-road, 28 in Clerkenwell-road, 1 in Hart-street, seven in Bloomsbury-square (South), one in Vernon-place, 13 in Great Queen-street and 18 in Southampton-row (Vernon-place and Russell-square), one 300 c.p. lamp in Endell-street, and four 180 c.p. lamps in Queen-square, Bedford-row, Endell-street, and Onslow-street, and 716 90 c.p. lamps in the remaining streets of the borough, giving a total of 966 electric lamps on 957 columns, against 879 gas lamps on 879 columns. The report further stated that the present tender was made on a specification prepared by the borough surveyor which was approved by the Council on March 8 last, and provided for all new lamps and fittings and contained proper conditions for the protection of the Council in all respects, and on the basis of a 10 years' contract determinable at the end of the fifth year by the Council, on payment of £4,400 fifth and smaller sums in subsequent years. In a letter which accompanied the tender, the companies stipulated, however, for the deletion of clauses 34 and 35 in the specification, otherwise the annual payment would be increased 10 per cent. Clause 28 provided for the imposition of a fine upon the contractors in the event of the nominal candle power falling more than 10 per cent. on an average of 30 lamps taken on three successive nights. Clause 35 provided that the contractors shall adopt any subsequent improvement in burners, lamps, or appliances that may be made, without additional cost to the Council. As regards clause 34, the opinion of the Committee, the condition was too onerous, and might well be deleted. They were strongly of opinion, however, that clause 28 should be adhered to, as upon that clause it depended entirely whether the Council should retain any control over the efficiency of the lighting. Negotiations had taken place with the companies on the point, but without any satisfactory result. They concurred in the opinion of the Works and General Purposes Committee that a proposed new clause by the companies was quite unacceptable, as not only did it allow of a not reduction of no less than 20 per cent. in the candle power, but the penalty for exceeding this limit would be so trifling and difficult of enforcement as to be practically useless. They were unable to recommend any other than a general scheme for the whole borough, and they, therefore, saw no alternative but to accept the condition on which the companies were willing to be bound by clause 28 as originally drawn, *i.e.*, by making an extra payment of 10 per cent. on the contract price, which would therefore be £7,645, instead of £6,950 per annum. They recommended the joint and several tender of the Gas Light & Coke Co. and the Metropolitan Electric Supply Co. for lighting the streets of the borough for

Digitized by Google

years for £7,645 per annum, subject to the deletion of clause 35 in the specification, and the amendment of the schedule of lighting as proposed by them, be accepted, and that the seal of the Council be affixed to the necessary contract to be prepared by the town clerk.

In a report on the subject the Finance Committee advised that before the Council adopt the recommendation of the Committee of the Council with regard to improved lighting the words "subject to the consent of the London County Council being first obtained to the form and principle of the Contract" be added to the recommendation of the Committee, or alternatively that the recommendation of the Committee be referred back for negotiations with the Companies to ascertain the cost of purchasing columns, lamps, lanterns, &c., outright.

The Mayor (Mr. HORATIO PORTER) moved the adoption of the report of the Council in Committee.

Mr. C. E. GREEN reviewed the circumstances which had led up to the present situation and said the Works Committee had lost the opportunity of a system of obtaining increased lighting for the Borough at a saving of £2,000. He thought the Council could still obtain a tender which would be more economical than the present tender, which he urged should not be accepted.

Mr. MAY CLARKE said the Committee had never asked for more than £9,000. The lighting companies sent in tenders for a light exceeding that, and the Council had either to accept or reject; they had no power to amend. He was still of opinion that the lighting of the side streets was insufficient.

Mr. N. GLAVE said the Borough was not properly lighted. The principal lighting came from the public houses and the theatres. Everybody's tendency was to give more light, and if they wanted more light it would have to be paid for. He thought the recommendation before them was the best solution of the problem. In addition it would give an excellent idea as to which was the ideal system. He thought strongly that the tender should be accepted. The increased expenditure was comparatively small as they were getting three times the light.

Mr. J. H. WRENTMORE said the report ought to be referred to the Works Committee for consideration and further report.

Mr. W. GIBBS KENT supported the suggestion that the report be referred to the Works Committee, together with the report from the Finance Committee.

Mr. W. G. COXEN said the approximate cost of lamps was £9,000 and if they made a capital expenditure to cover that item their annual expenditure would be reduced by £1,000 at least.

Mr. MAY CLARKE said the matter of the £9,000 referred to by the Finance Committee had never been before the Works Committee.

After further discussion the matter was referred to the Works and General Purposes Committee for further consideration and report.

LEGAL INTELLIGENCE.

National Telephone Co. v. H.M. Postmaster-General.

On Wednesday the Court of Appeal (the Master of the Rolls and Lords Justices Farwell and Kennedy) commenced the hearing of the cross appeals from a judgment of the Railway and Canal Commission in this case (reported in THE ELECTRICIAN for June 2, p. 308).

The Railway and Canal Commission held (by a majority) that the notices given by the Postmaster-General with regard to the three London exchanges were good but that the others were bad as being too vague, and that was no answer to say that it would have been difficult to have stated more explicitly the plant, &c., objected to.

The Attorney-General, the Solicitor-General and Mr. Branson appeared for the Postmaster-General, and Sir A. Cripps, K.C., Mr. Danckwerts, K.C., Mr. Morton, K.C., Mr. Forbes Lankester, K.C., and Mr. H. Gaine for the Telephone Company.

The ATTORNEY-GENERAL, in opening the case for the Postmaster-General, said the question their lordships had to determine was what construction to be put upon certain clauses of the agreement for the purchase of the Company's undertaking. There were substantially two points involved. One was as to the validity of certain notices of objection by the Postmaster-General and the other point was as to the meaning of certain words in the agreement, and the particular point involved in the appeal was whether the Postmaster-General was right in saying that he was not bound to take over plant which was duplicated. In other words that the Postmaster-General was not bound to take over plant which was not necessary for his requirements because he had already got plant which was sufficient to supply the wants of his subscribers. Whatever the result of the appeal was they had to go back to the Railway and Canal Commission in order to determine questions of fact of considerable complexity which were involved in the judgment of the Commission. He submitted that it was a reasonable construction to be put upon the phraseology of the agreement to say that the Postmaster-General was bound to take over the whole of the land, plant and buildings of one of the Company's exchanges when the Postmaster-General had got practically all but the corner the whole equipment necessary for the purpose of supplying his subscribers. He contended that the Postmaster-General was not bound to take over the plant, &c., in any area where the Post Office was sufficiently supplied with plant. What had to be examined were the needs of the telephone service of the Post Office at the date when the Company's business was taken over by the Post Office and not. The real point for decision was to ascertain the needs of the Post Office for carrying on the combined business of the Company and the Post Office at the date when the business of the Company was taken over by the Post Office.

The Solicitor-General followed on the same side. Sir A. Cripps opened the case for the Telephone Co., and the case was proceeding when we went to press.

Hartlepool Electric Tramways (Ltd.) v. Mayor and Corporation of West Hartlepool.

Mr. Justice Bray had this action before him again on Wednesday. The facts were reported in THE ELECTRICIAN for May 12, p. 183.

Mr. ATHERLEY JONES, K.C., for plaintiffs, said the subject-matter of the action had already been before his lordship in the form of a special case, when it was pointed out that the award of the arbitrator was not in statutory form, and a suggestion was made that some arrangement might be come to between the parties, so that the issue between them might be properly formulated. It had now been agreed that the value of the undertaking should be taken to be £12,963, and the only question remaining for decision was whether the purchase money was payable to the promoters (Messrs. Sellon and Francis Ashby), or to plaintiff company, who were the assigns of the promoters. There was no legal assignment to the company by the promoters, but there was an equitable assignment. No sanction was obtained from the Board of Trade, as required by Statute. It was contended that Messrs. Sellon and Ashby were, and still remained, promoters of the undertaking, but that they had no property whatever in the undertaking, and, therefore, could not receive payment for that which they did not possess. A second contention was that plaintiff company were mere trespassers, inasmuch as no statutory assignment had been executed to them, whatever the rights between the plaintiff company and the promoters might be.

Mr. BALFOUR BROWNE, K.C., for the Corporation, submitted that there was no one to whom the Corporation could pay the purchase price.

His LORDSHIP: I cannot order payment of the money, but I can order specific performance. Then a question will arise as to the title to the tramways.

Mr. BROWNE: We have agreed the value of the things belonging to the promoters.

His LORDSHIP: I think the payment ought to be made to the promoters. No one else has any right to bring this action.

Mr. BROWNE: The promoters were paid out by plaintiff company, and the company cannot be said to have constructed the lines for the promoters.

His LORDSHIP: To whom does the tramway belong?

Mr. BROWNE: To nobody. Plaintiffs have no title to it.

His LORDSHIP: The promoters have not lost their power to work the tramway. Whatever the rights may be between the two people one does not know; but the question in law is, who has the power to work the tramways?

Mr. BALFOUR BROWNE said he thought the promoters had lost their power to do so through not exercising their right. Neither the promoters nor plaintiff company had any property to sell. Plaintiffs might have property in the rails, if they liked to take them away. Plaintiffs ought to get a private Act of Parliament or a provisional order, and then the Corporation would pay the money.

Mr. ATHERLEY JONES: I do not think a provisional order is required. All we need is the sanction of the Board of Trade.

His LORDSHIP reserved judgment.

PARLIAMENTARY INTELLIGENCE.

COAL MINES BILL.

The Standing Committee of the House of Commons on this Bill resumed its sittings on Wednesday.

Sec. 32 (1*b*) provides that no lamp or light other than a locked safety lamp shall be allowed or used in any seam (except in the main intake airways, within 200 yd. from the bottom of the shaft) in which an explosion of inflammable gas causing any personal injury whatever has occurred within the previous 12 months.

Sir W. MENZIES moved the omission of this sub-section, and stated that the miners, mine-owners and mine-managers in Scotland were unanimously in favour of this being done.

On a division the sub-section was carried by 19 votes to 18.

Mr. MASTERMAN then proposed the following addition to the sub-section:—"unless an exemption is given by the Secretary of State on the ground that on account of the special character of the mine the use of safety lamps is not required." This exemption would embrace, among others, the thick seams in South Staffordshire and such places as the Cleveland iron mines and the shale mines in Scotland.

The amendment was agreed to, and the clause as amended added to the Bill.

Corporation of London (Bridges) Bill.—In the House of Commons on Wednesday this Bill, which provides, amongst other things, for the building of a new bridge across the Thames and the construction of a new street with tramways from North to South London, was re-committed for further consideration.

Gréater London Railway Bill.—A Select Committee of the House of Commons resumed consideration of this Bill on Wednesday, when further evidence in opposition to the scheme was given on behalf of the Finchley and Hendon Councils.

COMMERCIAL AND INDUSTRIAL SECTION

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Aberdeen.—The Council have decided to replace with new car bodies fitted with top covers four of the old horse cars, at a cost of £425.

Aldershot.—An inquiry will be held into the application of the Council for sanction to a loan of £2,500 for the electricity undertaking.

Application for Extension of Patents.—Application is being made for an extension of the term of the patents Nos. 1,020 and 1,022/1898, granted to Charles Hy. Stearn for "Improvements in the manufacture and production of a filamentary material and fabrics therefrom" and for "Improvements in the manufacture and production of a filament in film, sheet or web form." Objections to the chambers of Mr. Justice Parker, Royal Courts of Justice, London, by July 22.

Barnet.—The Council have asked the Board of Trade to appoint an arbitrator to deal with the dispute with the North Metropolitan Electrical Power Distribution Co. as to the price for current for lighting under the existing agreement between the parties.

Colchester.—The Electricity Supply Committee have adopted a scheme of hiring out domestic electrical apparatus, flat-irons, &c.

Coronation and Annual Holidays.—We are informed that the following arrangements have been made for Coronation and annual holidays:—

Willans & Robinson's offices and works will be closed on June 22, 23 and 24 and from Friday, Aug. 4, to Monday, Aug. 14. A small staff will remain to deal with urgent correspondence and replace parts, but the company ask that no goods be despatched to arrive during the above periods.

Pope's Electric Lamp Co. announce that their works will be closed on June 22 and 23 and (for the annual outing) on June 24.

Coronation Illuminations.—*Bristol* and *Colchester* Corporations will supply current for Coronation illuminations at 1½d. per unit.—At *Colwyn Bay* current will be supplied free for outside illuminations during the Coronation festivities.—In another column we give some particulars of tenders accepted by *Wigan* Council for material for Coronation illuminations.—Residents at *St. Anne's-on-Sea* will be supplied with current at cost price.—The sea front at *Llandudno* will be brilliantly illuminated.—The front of *Portsmouth* town hall will be outlined with coloured electric lamps.—*Walthamstow* will supply during Coronation week at 1½d. per unit or (alternatively) at 1d. per 8 c.p. lamp for "illumination" purposes.—The festoons of electric lamps along the whole of the *Brighton* sea front are to be lighted nightly for a month from June 22, the whole of the illuminations including those at the Pavilion, the Mayor's Parlour and the Old Steine comprising from 10,000 to 11,000 lamps.—At *Hove* the sea front, town hall and other places will be illuminated electrically.

Dudley.—The Corporation have adopted the recommendation of the Tramways and Lighting Committee to extend the electricity generating plant and mains at an estimated cost of £8,140.

Kilkeel (Ireland).—At a recent public meeting it was unanimously decided to form a public company for the erection of electricity works. Nearly the whole of the required capital was subscribed on the spot.

Light Railways.—The County of Hertford (Cheshunt) Light Railways Order (authorising the abandonment of part and revival of powers with respect to the remainder of the railway authorised by the 1906 order), and the Tarporley Light Railway (revival and extension of time) Order (reviving powers for purchase of land and extending period for same and for completion of works authorised by 1906 order) have been submitted to the Board of Trade for confirmation. Objections to the Board by July 7.

Manchester.—On Tuesday an inquiry was held into the application of the Corporation for sanction to borrow £12,186 for plant for the electricity department and also to expend on mains and service sums amounting to £50,000 which the Council had been authorised to borrow for certain other purposes.

The Town Clerk said that the £12,188 was the balance unborrowed at unsanctioned of £130,500, in regard to which an application was made 1908. The £50,000 was part of a sum of £75,000 authorised on June 1 1901, to be borrowed for street lighting. The Committee had not thoug it necessary to spend the £75,000 on street lighting, and they now desir to divert £50,000 for mains and services. He gave particulars of t present financial position of the electricity undertaking and said that i expansion rendered necessary the expenditure on mains and services an on the extension of the plant at the Stuart-street generating station.

Metal Filament Lamp Patent Litigation.—We have received for pu lication letters in regard to an alleged infringement of Letters Pate Nos. 23,899 of 1904 and 8,563 of 1907 owned by the Osram Lam Works (Ltd.) The letter addressed by the solicitors to the Osr Lamp Works (Ltd.) asks for an undertaking by the Corona Lam Works Co. to cease infringement and to deliver up any infring lamps in stock and also to provide full information as to the num and power of the lamps sold, in order that the amount of damage m be estimated. The reply of the solicitors to the Corona Lamp Wo Co. expresses surprise at the allegations of infringement, affirm that the Corona Co.'s lamps are manufactured by an altogether d erent method to those set out in the Osram Patents of 1904 and 1 respectively. The letter proceeds to intimate that the Corona are prepared to indemnify their customers against any proceed by the Osram Co. in regard to the "Corona" or "Mascot" lam and further that the Corona Co. will meet and defend any ac brought against them in this respect.

Newcastle (Staffs.).—Sanction to a loan of £5,400 for additi generating plant has been applied for by the Council.

Olympia Electrical Exhibition.—Announcement is made that a Electrical Exhibition at Olympia from Sept. 23 to Oct. 21 the Office telephone department is providing telephonic facilities exhibitors. Applications have to be sent in within the next few d

Penmaenmawr.—The Board of Trade have deferred the que of the revocation of the Provisional Electric Lighting Order.

Presentation.—The staff of the Lewes electricity Works have sented a barometer to Mr. J. Morris on his marriage.

Rail-less Trolley Traction in Yorkshire.—Arrangements have made for the formal opening on Tuesday next of the trackless t car services in Leeds and Bradford.

The service in Leeds will be to Farnley, and in Bradford from La dyke to Dudley, a distance of about a mile and a quarter. The ge details of the installations have been provisionally approved by Board of Trade, and the preparations are now practically compl It is intended that the opening of the lines in both Leeds and Brad shall take place at noon on Tuesday. The Lord Mayors of Leeds Bradford will open the routes in their respective cities and a joint lunc will afterwards be held in the Leeds Town Hall.

Redditch.—On the recommendation of the electrical engineer W. J. Ferguson) the Council have decided to put in a steam altern in place of two gas engines and a 100 kw. gas-driven alternator to carry out other extensions and improvements of the plant at a of £5,850.

Rotherham.—It is proposed to wire the outside market for electric light.

Stafford.—It was reported on Tuesday by the Gas and Electr Committee that the gross profit on the electricity undertaking fo past year was £2,734, and after meeting capital charges there w net profit of £607. It was decided to pay a bonus of 10·4 per c on the wages of the men employed at the electricity station.

Stoke-on-Trent.—An inquiry was held on Wednesday into the plication of the Corporation for sanction to borrow £60,000 for erection of a new three-phase generating station.

For the Corporation, Mr. THORN DRURY stated that there was an ur necessity for extensions of the electricity undertaking and the me proposed to be adopted was to erect a three-phase high-tension p station near the present Hanley electricity works, and to convert

Digitized by Google

other four works in the area into sub-stations for transmitting the current. The details of the proposed expenditure were: Buildings £9,415, generating station plant £29,056, sub-station plant £8,435, e.h.t. mains £13,094 total £60,000. It certainly was not possible to face another winter without making provision for an increased supply, and he claimed that the course proposed to be adopted by the Corporation was the only one from the point of view of both economy and efficiency.

The Chairman of the Electricity Supply Committee (Mr. H. LEESE) and the borough electrical engineer (Mr. C. H. YEAMAN) gave evidence in support of the application. Mr. Yeaman said if the Council were going to meet their obligations an extension of plant was absolutely necessary. Extensions inside the existing works would not be economical, and he considered the scheme sound from an engineering point of view.

Mr. J. F. C. SNELL, consulting electrical engineer, also gave evidence in support of the scheme.

The North-Western Electricity & Power Gas Co., the North Staffordshire Railway Co. and others opposed the scheme.

Councillor J. S. GODDARD said a large body of ratepayers in the area were against the scheme.

Mr. C. S. VESEY BROWN, consulting engineer to the North-Western Electricity & Power Gas Co., said they were prepared to supply electricity in bulk to the Corporation. No capital outlay on the part of the Corporation would be necessary as the power company were prepared to lay mains and put down the transformer plant.

In reply to the Inspector (Mr. H. Ross HOOPER) witness said the company had no works at present. They had arranged to buy power from the Cockshead Colliery and from Messrs. Robert Heath & Sons' ironworks, but there was no legal agreement.

Mr. GRAHAM MILWARD said the borrowing of such a large sum would seriously impair the credit of the borough now and affect their future borrowing. Some parts of the borough at present were the highest rated areas in England. This loan was proposed at a time when the borough was unable to bear the pressure.

Mr. E. S. MARSHALL, for the North Staffordshire Railway Co., said the railway company viewed the financial position of the Corporation with great alarm, not only because they were the largest ratepayers in the area and had to pay large sums themselves, but because their welfare was bound up with that of the district.

Walsall.—Sanction has been received to the borrowing of £17,840 for the electricity undertaking, less £3,330 in respect of superseded plant and buildings.

Wharfedale (Yorks.).—A company is to be formed to supply electricity in the Wharfedale district, including Otley, Burley, Ilkley, Menston, Guiseley, Yeadon and Baildon.

Messrs. Newstead & Wade, solicitors, Otley, are acting for the promoters, and already two or three of the Councils interested have passed favourable resolutions. Yeadon Council have deferred the matter for a month pending receipt of further information. It is proposed that the maximum charge for current shall be 5d. per unit for lighting and from 3d. to 4d. per unit for power. The statutory notices to the Councils are to be served during the month.

Wimbledon.—Electric current will be supplied to consumers in Malden and Coombe at 6d. per unit for lighting and 2d. for power or heating with 1s. per quarter for a meter not exceeding 25 amperes and 2s. 6d. per quarter for a meter exceeding 25 amperes.

Application is to be made to the L.G. Board for sanction to borrow £50,000, the estimated amount required until March, 1914, for mains and house services (£4,225), meters (£895) and transformer sub-stations £650.

Current for external lighting will be supplied at 3d. per unit, provided consumptions for not less than 100,000 units per annum are received by July 31.

The Arc Engraving Co. offered a uniform rate of 1d. per unit for all energy supplied to their factory, with a guarantee of a minimum consumption of 30,000 units per annum. The power rate in force for the time being is to be charged for all energy supplied to the company as from July 1 last.

A subcommittee has been appointed to meet Messrs. Handcock & Dickes, representing the Fixed Price Lighting Co., to discuss an arrangement between the Corporation and the company for the supply of energy to private houses for lighting at a fixed price per annum.

Wireless Telegraph Notes.—The "British Australasian" is responsible for the following:—

Barrier to Wireless.—It has been ascertained that Cape Otway is a barrier to wireless communication with Melbourne. Mr. C. A. Hill, wireless operator on the "Themistocles," thinks that iron or other mineral deposits on the high land of the Cape intercept the messages and prevent them. On successive voyages he has been unable to call up wireless ships in the bay when on the other side of Cape Otway, but immediately the parallel was crossed he could speak to them with ease.

The Australian Commonwealth Government recently decided to appoint a wireless telegraphy expert in Australia, and we are informed that the candidates for the position are very numerous and these have now been submitted to the Commonwealth consulting engineer (Mr. Charles Bright, F.R.S.E.) for his consideration and recommendation.

York.—The L.G. Board have sanctioned a loan of £10,700 for extensions of the electricity undertaking.

In forwarding the sanction, the Board state that they are advised that the plant which it is proposed to instal will have the effect of superseding the small 74 kw. alternator sets at present in use, on which there is debt outstanding. They also learn that there is practically no reserve or depreciation fund to meet the renewals of plant which must shortly become necessary, and that, although a profit was made last year on the undertaking, the greater part of it was applied to relief of rates. In these circumstances it is with considerable hesitation that the Board have decided to sanction a loan for the full amount required for the new plant, and they urge upon the Council the necessity for the establishment of a reserve or depreciation fund in order to provide for the renewal or replacement of plant as it becomes worn out or obsolete.

Outing.—The employés of the Ealing Corporation electricity department had their annual outing last week.

The party travelled to Box Hill, where an excellent programme of sports was carried out, and at a luncheon which took place the borough electrical engineer (Mr. J. D. Knight) said the past year had been a trying one for their electricity undertaking and all their energies would be required in the coming years to make their success continuous and progressive. Mr. Knight subsequently presented the sports prizes and mentioned the impending departure of Mr. R. Golding (assistant engineer) for Australia.

COLONIAL AND FOREIGN NOTES.

Argentina.—A new concession (cancelling the concession they previously obtained) has been granted to the Buenos Ayres Western Railway Co. for an underground electric railway in Buenos Ayres from Calle Sadi Carnot to the port tramways, and two additional lines between Caballito and Moreno.

Australasia.—The "Australian Mining Standard" says Ballina (N.S.W.) electric lighting plant, which has been in operation about three months, was installed by the Provincial Electric Lighting Co., of Sydney, and consists of a 75 H.P. Crossley suction gas plant, and a 40 kw. d.c. generator giving 84 amperes at 480 volts and a battery of 264 cells

Ararat (Victoria) Council have appointed Messrs. G. B. Lincolne and J. K. MacDougall as consulting engineers for their proposed electricity undertaking.

In giving further evidence before the (Melbourne) Metropolitan Traffic Commission, Mr. R. P. Wilson said he recommended the conduit system of tramways for the city itself. The cost of the overhead system might be taken as £8,000 per mile of single track and the conduit system as £18,000. As a temporary expedient electric motors might be substituted for the present engines working the cable tramways in streets where the general traffic would not permit of the speed of the cars being accelerated. For traction and power there should be only one power house in Melbourne district, as that would give the best diversity factor. The Malvern cars (8 ft. 3 in. wide) were abnormal, 85 per cent. of the world's tramcars were 6 ft. 6 in., and in Melbourne the cars were generally 7 ft. 3 in. It would be better to sacrifice the Malvern cars for the sake of uniformity than put the £2,000,000 worth of cable cars out of commission.

Mr. Wilson, who is to submit a report to the Commissioner, has been allowed a fee of 250 guineas for the information he has given to the Commissioner and to the Railways Standing Committee.

The Tumberumba (N.S.W.) Railway League has asked the Public Works Committee not to furnish a report on the electrification of the proposed railway to Tumberumba until it has obtained a departmental report on the desirability of establishing a power station on Tumberumba Creek, as it is suggested that the larger and permanent water supply thus obtained would enable much greater power to be generated.

The city electrical engineer (Mr. H. R. Forbes Mackay) recently explained to Waverley Council a scheme for the extension of the Sydney municipal electric supply mains to Waverley, four miles from the city. The cost of laying underground mains was, he said, prohibitive, as underground mains in the city cost six times as much as overhead mains. He believed he could supply electricity in Waverley cheaper than the present gas supply. In the streets where he laid mains public lamps would be lighted at £3. 7s. 6d. per annum for light equal to the ordinary gas lights on a 10 years' agreement.

In giving evidence before the Royal Commission recently appointed to inquire into the system of letting N.S.W. Government contracts, Mr. A. Berckelman, secretary and ex-member of the Stores and Supply Department, said there was no such thing as favouring certain firms. For contracts from £20 upwards advertisements were inserted in the papers inviting tenders. In buying machinery the best expert advice was obtained, and if the experts decided that some different class of machine would suit the particular department better than the class the principal of the department had asked for, the whole matter would be placed before the Minister, and he would decide. A prime cost item was that which could not be described so as to be included in the specification. A sample room should be provided for prime cost items. He thought the Public Works Department should follow the example of the Stores Supply Department, by having the articles sent to a Government depôt and examined. Mr. Thos. Raw, assistant engineer in the Government Architect's Branch, said in contracts over which he had control the contractor obtained quotations from various firms for the article required, and these

Digitized by Google

were submitted to witness, who passed them on to the Government architect with recommendations. It was the custom to select the lowest tender or give a good reason for not doing so. Mr. Wm. Corin, electrical engineer of the Public Works Department, said in a case like that of a contract at the Coast Hospital (which was under his supervision), which was let, say, two years before it was finished, he thought prime cost the best way to deal with items which could not be put into the original contract. Everything possible should be put into the contract, but there should be a clause with regard to some items which the Government should supply, and possibly another clause including prime cost items, and these also, in the majority of cases, might be put down to be supplied by the Government. In the Coast Hospital contract there were prime cost items for lamps. There was nothing to prevent a successful firm paying 10 per cent. discount to a contractor. If the contractor were directed to buy lamps from a firm at a price and the firm made the contractor a present the Department would know nothing about it. Mr. T. B. Cooper, secretary to the Public Works Tender Board, said tenders under £200 were managed by the departmental officers and those over that amount by the Minister, who was the final authority. It would not be possible for a firm to see the tenders and then submit a lower tender. In the case of competitive quotations, the superintendent of stores consulted a list of registered firms, and called for quotations, which, if suitable and under £10 in cost, would be accepted by him, but if over £10 would first have to be passed by the Minister. If a firm wished to become registered they approached the superintendent of stores.

Rutherglen (Victoria) Council have decided to adopt electric lighting in the streets and also to provide a supply for private consumers. The capital cost is estimated at £2,500.

To systematise the carrying out of various works necessitating the opening of roads in Sydney a conference was recently held of the authorities concerned, including representatives of municipal and Government departments dealing with public works, electricity supply, tramway, water and sewerage and postal works and the Sydney & Suburban Hydraulic Power Co.

The Municipal Council of Vaucluse (a suburb of Sydney) recently decided to light the Town Hall electrically for five years, and a company will probably be formed to light the military buildings and streets.

Brazil.—A consular report from Rio de Janeiro states that the acting Consul-General has become more and more convinced of the uselessness of a large proportion of the catalogues sent to Rio.

The majority of these (he points out) do not give sufficient information of the right sort. The article is well described (in English), but discounts, modes of payment, &c., are not mentioned. If a local house cannot give a price immediately the chance of trade is often lost. Not more than three or four catalogues in Portuguese have been received at the Consulate. Whatever trade foreign competitors have taken from British traders in Brazil has been the result of close study of the local conditions. The United Kingdom supplies about 26 per cent., Germany 15 per cent., the United States 12 per cent. and France 10 per cent. of the total imports.

Congo State.—A proposal has been made for the construction of an electric railway from Matadi to the neighbouring hills to enable the Europeans to live out of town.

Egypt.—The "Egyptian Gazette" states that the Cairo Tramways Co. carried 53,492,219 passengers during 1910 (increase 4,000,000) and the receipts were £276,866 (an increase of 8 per cent.). The length of the lines is 344 miles (increase nearly one mile).

The Sloan Electrical Co. have removed their Manchester office from 16, John Dalton-street to 16 and 16A, Jackson's-row. The head office of the company is at Conradty House, 12, Golden-lane, London, E.C.

German Consular Service.—"Engineering" states that the German Government is preparing an important reform of the German diplomatic and consular service, in the creation of new posts as technical attachés to the Empire's legations. These new offices will be filled by engineers and technical experts, and it is proposed to place these technical attachés on the same footing as the usual diplomatic attachés. Their work will be, as quickly and as thoroughly as possible, to keep themselves posted with all technical inventions and progress of any importance in the different countries, with reference to which it may be considered that they are of value in industry or commerce. The two first appointments are likely to be in connection with the German Embassies in London and Washington. It is also under consideration to attach technical experts to some of the consulates.

Japan.—The acting British Commercial Attaché for Japan (Mr. R. Boulter) says, in a communication regarding the production and manufacture of copper in Japan, that the Japanese importing houses with branches in London and New York have secured many orders for small motors, &c., and they have for the most part filled them with American and German machinery.

The reason appears to be that the initial cost of such machinery is very often cheaper than that of British machinery, although the latter would probably prove cheaper in the long run, taking into consideration the working capacity, expenses for upkeep, &c. The point of view of the Japanese mining engineer is probably that, so far as he can see, the British machinery is the most expensive of the three as regards initial cost, and he has not sufficient experience of its working to justify his recommending its purchase when makers of other nationalities offer what is apparently the same article at a lower price. Moreover, Japanese copper mining engineers when travelling abroad would naturally spend more time in America than in England, as they find in the former country the opportunities of practical study for which they are travelling; they thus become accustomed to the working of American types of machinery. Another point is that German merchants are stated to be willing to give more liberal terms as to credit than British firms give. As regards power stations, for which contracts would naturally be much larger, tenders are usually invited from engineers of various nationalities.

Paris Telephone Service.—A measure has been introduced into the French Chamber for the extension of the telephone service of Paris, at an estimated cost of Fr.11,667,000.

Roumania.—A consular report on the Braila district states that the electrical goods imported during 1910 include dynamos, motors, rotary converters, accumulators, arc lamps, telegraph and telephone apparatus, bells, batteries for medicinal and chemical purposes, switches, wire and insulated cables, &c., incandescent lamps and porcelain insulators. Ventilators are used to some extent in banks, hotels, hospitals and public institutions.

The steady development of home industries in Roumania is favourable to the import trade in electrical goods, but there is keen competition between the United Kingdom, Germany, Austria-Hungary and France. Manufacturers should be represented in Roumania. The import business in the Braila district is chiefly carried out through commission agents, who are of great assistance to commercial travellers and to the firms that they represent, but firms should send out their own representatives to establish their first connections; and it is necessary for such men to be capable of transacting their business, failing Roumanian, either in German or in French, the former for choice. The foreign agent or traveller is an expert; he speaks the business language, has circulars and price lists in that language, and will wait upon the would-be buyer at his own shop. He can further give him indulgent terms owing to being in continual and personal contact with him, visiting him several times a year.

Spain.—D. Fernando G. Gongora has been authorised to make surveys for the construction of an overhead electric tramway in Malaga.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Brighton.—For the year ended March 31 the traffic revenue of the tramways department was £49,124 and sundry revenue £1,623, a total of £50,747, against £51,358.

The working expenses were £37,609 (against £37,069) and the gross profit was £13,078 (against £14,289). After paying interest (£7,918) and sinking fund charges (£5,023) there was a balance of £137; 10,708,184 passengers (against 10,759,947) were carried and the car-miles run 1,126,676 (against 1,130,685). The number of units of electricity used was 2,023,109 (against 1,938,305), or 1·79 per car-mile (against 1·71).

Burnley.—The total capital expenditure on the tramways department for the year ended March 31 is £206,134, an increase of £7,769 over 1910.

The total revenue for the past year was £65,817, including £65,570 (against £65,295) from traffic receipts. The working expenses were £42,574, leaving £23,243 as gross profit. After paying interest, sinking fund and income tax, placing £5,000 to reserve and setting aside £1,000 for contingencies, and deducting accountant's fees, &c., the balance (£499) was placed to reserve; 13,107,830 passengers were carried, against 12,911,113, and 1,306,860 car-miles run, against 1,263,118.

Devonport.—In submitting the annual report of the Electric Power Committee at the meeting of the Council last week, the chairman (Ald. J. B. Love) said that there had been a large increase of new consumers during the past year, and also in the consumption of current.

Ald. Love said that they expected that the increasing demand would continue in the future, and should mean corresponding increases in profits. After paying all expenses, including interest (£3,624) and sinking fund (£3,014) and contributing £833 (against £445) for relief of rates there was a net balance of £26. 2s. 11d. which the Committee recommended be put to reserve fund. After paying £1,540 for the mechanical stokers, the reserve fund would stand at £8,352, which was sufficient for contingencies.

Dudley.—For the year ended March 31 the total capital expenditure was £1,877, bringing the total to £97,310.

It was reported to the Council on Tuesday that there was a decided improvement in the working of the undertaking. With the exception of the supply for traction there had been an increase in the output. The income was £13,009 against £12,991, the gross profit £5,939, an increase of £135. The undertaking had been debited with £500, the first instalment of the cost of the arbitration in reference to the price of tramway current, thereby reducing the gross profit to £5,459. Interest and repayment of loans came to £6,665, leaving an adverse balance of £1,206.

Mr. H. W. HUGHES, chairman of the Tramway and Lighting Committee, explained that if the tramway company had been supplied at the old rates and there had not been any arbitration costs to pay, the income would have been £14,018, the gross profit £6,968, and net profit £302; whilst had the conditions of traction supply remained as in preceding years the undertaking would have advanced from a net deficit of £609 to a net profit

Digitized by Google

of £592. The arbitration expenses amounted to about £2,000, payment of which it was proposed to distribute over four years. The aim of the Committee had been directed principally towards the idea of supplying electrical energy so cheaply for lighting and power as would enable manufacturers to employ it to keep their factories going full time, thereby increasing the number of workpeople and indirectly promoting the prosperity of the town.

Dundee.—The accounts of the electricity department for the past year show a net profit of £7,254.

The report states that the cost of coal was 7 per cent. higher than in 1909-10. Units sold were 7,720,018, an increase of about 1,500,000 or 24 per cent. Units sold for power represented the largest part of the increase, units for lighting showing an increase of 170,000.

Eastbourne.—The income of the electricity department for the year ended March 31 was £24,522, against £25,144.

The working expenses were £10,969 (against £11,282) and the gross profit was £13,553 (against £13,861). Interest and sinking fund charges came to £11,340 (£11,661), leaving a nett profit of £2,213 (£2,200), out of which £1,500 has been transferred to reserve. The gross capital outlay is £220,985.

The annual report of the borough electrical engineer (Mr. J. K. Brydges) states that the equivalent of 122,000 30-watt lamps is connected (against 111,755 in 1910), an increase of 11,235, and included 97 arcs, 17 double and one three-light metal filament lamps for street lighting, 140 motors and 222 radiators. During the year 23 motors of 134 H.P. were connected, and during the past six months 74 radiators were added owing to the reduction in the price of current from 2½d. to 1½d. per unit. There are 1,758 consumers, against 1,584. The units sold for private lighting show a small increase, against a decrease of 2·6 per cent. The revenue from private lighting shows a decrease of £961, mainly due to a reduction in the price from 3d. to 5d. a unit, but the revenue from power and heating increased by £316, of which £148 was from radiators. The works cost are 1·2d. per unit, against 1·36d., and the total costs 1·79d., against 1·92d.

Epsom.—The accounts of the electricity department show capital expenditure £40,040 (increase £533), of which £11,791 has been extinguished.

Revenue was £5,954, working expenses were £2,703, and gross profit was £3,250 against £2,903 in previous year). After meeting capital charges the net profit was £510 (£185). Units generated were 321,236 (299,83), the total sold being 274,669 (250,810). The maximum supply demanded was 217 kw. (198 kw.).

The report of the engineer, Mr. A. C. Gilling, states that during the year 50 of the ordinary public lamps and 12 arcs have been changed over to metallic, leaving 96 still switched from pillars. The total number of (equivalent) 8 c.p. lamps connected is 21,828. Revenue per (mean) unit is 3s. 6s. 3¾d.), the drop being due to increased sales for heating purposes at a cheap rate. Works costs were 1·477d. (1·522d.), and total costs 2·266d. (2·177d.). Capital charges were 2·393d. (2·599d.). The figures quoted show a steady increase, and apparently the danger of loss of revenue from the adoption of metallic filament lamps is past.

At a recent meeting, the Council adopted the report and accounts, and congratulated the Committee and the officials on the result of the year's working.

Lincoln.—The accounts of the electricity supply and tramways undertakings for the year ended March 31 were approved by the Council last week.

The total income of the electricity department was £13,623, and included £7,597 from sale of current for private lighting, £638 from public lighting, £4,415 from power supply and £908 from the tramways department. The working expenses came to £6,331, leaving a gross profit of £7,292. After providing for redemption of debt (£1,945), dividends and interest £2,090, deficit on tramways (£153) and paying £2,000 in relief of rates, the balance (£1,170) has been transferred to depreciation account. The capital expenditure is £67,410 and the outstanding debt is £48,628. The units generated were 2,054,729 (against 1,918,790) and the units sold 1,830,482 (against 1,642,424). There are 34 arc and 92 metal filament lamps for street lighting, and the total maximum supply demanded was 365 kw. for lighting and 100 kw. for traction. There are 662 consumers (against 619) and the equivalent of 88,179 (against 74,253) 8 c.p. lamps connected.

The total revenue of the tramways department was £6,412 and the working expenses was £6,536. The expenses were £4,091, leaving a gross profit of £2,444. Interest and redemption of debt required £2,600, leaving a deficit of £153 which was provided out of the profit on the electricity undertakings. The capital expended is £54,049; 1,649,537 passengers were carried (against 1,599,751), 160,186 car-miles run (against 157,268), and 169,480 units of current (1·088 per car-mile) were used against 176,480 (1·123).

In the report of the city electrical engineer (Mr. S. Clegg) it is stated that there was an increase in the units sold under every head, except street lighting, the total increase being 178,058 units. There was a considerable addition under that of motors (473 H.P., of which 188 H.P. was for Clayton & Shuttleworth's) and 90,611 more units than in 1909-10 were sold. The total works costs were 0·835d. per unit (against 0·918d.) and the total costs, including interest and sinking fund, were 1·359d. (against 1·501d.) The cost of coal again showed a decrease (0·021d. per unit), this only owing to the use of automatic stokers on two low-pressure boilers. In regard to the tramways, there was a saving in traffic expenses, but there were small increases in repairs and maintenance, management and horse keep, and power, giving a total of 6·12d. per car-mile, against 5·95d. With this year's expenditure, the total amount spent since 1906 on the repairs of the "G. B" equipment is £539, an annual average of £108, or £18 a year in excess of the guarantee; but Mr. Clegg thinks that by the end of the period of the guarantee (10 years) the excess will disappear.

Manchester.—At the meeting of the Council on Wednesday it was reported there was a net profit of £27,573 on the working of the electricity undertaking for the year ended March 31, of which £15,000 has been transferred to district rate fund and the balance applied in defraying cost of special renewals.

The renewals suspense account has been augmented by £25,450. To permit of the extension of business, various additional borrowing powers amounting to £70,000 were obtained during the year. The total capital outlay is now £2,733,207, and the mortgage debt stands at £1,949,583. The annual sales total over 83,000,000 units. At the Dickinson-street and Bloom-street stations the first completed year of working with the large Tudor storage battery has resulted in a substantial reduction of the station costs. At the Stuart-street station the various works in connection with the independent water supply have been completed and put into successful operation for the major portion of the year. A contract has been entered into for a further turbo-alternator and satisfactory progress has been made with the various works. At Oldham-road, Bennett Side, Rusholme, Fallowfield, Levenshulme and Moss Side distributing stations extensions of converting plant and switchgear have been carried out. With the exception of the Bengal Mill, no extensions of note have been made on consumers' premises in connection with power supply. There was a net addition of 15 miles 858 yd. of mains and various alterations were made to the City network with the view of facilitating fault-localisation and improving the pressure balancing. The efficiency of the distributing system as a whole equalled 79·85 per cent., the quantity lost or absorbed in the mains and distributing stations being 20·15 per cent.

Middlesbrough.—In his annual report the Borough electrical engineer (Mr. H. M. Taylor) states that the net profit on the past year's working of the electricity department was £2,079, compared with £1,296 for 1909-10.

The price of coal, which increased 9d. per ton (7·5 per cent.) upon the previous year and other items including cost of repairs to boilers (£600) and labour troubles in the shipyards had been detrimental to the year's working. There was a gain through the re-adjustment of income tax, and through the reduction in the price of energy purchased from the Power Co. During the year a reduction in the price showed a decrease in revenue of over £200, but the effect was that a greater quantity of electricity was consumed. The number of consumers was 1,257, and the number of units sold was 2,021,586. The average price had been reduced from 2·24d. to 2·20d. per unit.

Nottingham.—The total revenue of the electricity department for the year ended March 31 was £94,882, including £91,915 from sale of current, £732 for public lighting and £1,748 for meter rent.

The expenditure was £52,010, including £17,739 for coals, £7,481 for wages, £4,413 salaries, £10,555 for rates and taxes, and £3,972 for repairs and maintenance. The gross profit was £42,872, of which £12,675 was paid for interest on consolidated stock and loans, £13,337 for repayment of loans, £2,416 sinking fund, and £15,350 was given as a contribution in aid of general district rate.

The report of the city electrical engineer (Mr. H. Talbot) states that the capacity of the plant at the three generating stations is 17,345 H.P., Talbot-street station, 8,925 H.P.; St. Ann's power station, 7,700 H.P. and Easteroft destructor, 720 H.P. There are 60·62 miles of distributing mains, an increase of 1·71 miles. The number of applications for a supply of electricity was 4,008, an increase of 207. The increase in the number of 32-watt lamps (or their equivalent) is 23,435, the largest for the past three years, the total at the end of the financial year being 410,322. The demand for electricity for power is maintained, 143 motors, aggregating 466 H.P., having been connected during the year, the totals being 1,183 motors and 4,635 H.P. The number of units sold was 11,944,527: for lighting 3,835,876 units, power 2,426,727 units and traction 5,681,924 units, an increase of 474,792 units; 52·02 per cent. of the units used for private lighting were at the reduced rate of 1½d. per unit. The works cost was 0·71d. (against 0·69d.), the total works cost 1·04d. (against 0·99d.) and the total costs 1·62d. (1·6d.) There was a decrease of 57,365 units used for lighting, compared with 192,204 units last year. The majority of the consumers are now using metal filament lamps, so that any further changes to this type of lamp should be compensated for by the continually increasing number of electric light users.

The receipts of the tramways department were £157,290, an increase of £2,354 (11·13d. per car-mile, as in 1910). The working expenses were £104,085. 14s. 7d., an increase of £5,922. 11s. 2d. (7·37d. per car-mile, compared with 7·06d.) Out of the balance (£53,204. 2s. 9d.) has been paid interest on stock and loans (£15,564), sinking fund (£18,823), reserve and renewal fund (£3,817) and £15,000 in aid of general district rate. The reserve and renewals fund, including interest on investments, amounts to £68,069. 12s. 8d. There was an increase in expenditure as follows: Rent, rates and taxes (£1,523), electrical energy (£1,405), wages of traffic staff (£743), maintenance (£2,641). Other items showed a decrease of £387, leaving a net increase of £5,923. Maintenance was £18,543 and included the cost of relaying the lines in Long-row and Queen-street, new junctions in Parliament-street and at the Sherwood depot, also new points and crossings of an improved design at all the passing places on St Ann's Well-road, and two passing places on Nottingham-road. The maintenance of cars includes cost of building and fitting 12 top covers and building an

Digitized by Google

additional snow plough. Overhead equipment maintenance included cost of renewing 8 miles of copper trolley wire, nearly all being replaced with wire of a larger size. 35,259,067 passengers were carried, an increase of 611,829, and 3,388,740 car-miles run, an increase of 48,191. The consumption of electrical energy for traction, car and depot lighting, works machinery and permanent way repairs was 5,681,924 units, costing £29,593. 7s. 1d., equal to 1·68 units and 2·11d. per car-mile, increases of 0·05 units and 0·07d.

St. Helens.—The annual report of the electricity department to March 31 states that there has been a very large increase in the output of energy, the total units sold being 4,138,000 units, an increase of 1,359,000 units (49 per cent.) compared with 1909–10.

The energy supplied for lighting increased from 420,000 to 454,000 (8 per cent.), for power from 916,000 to 2,115,000 (130 per cent.), and for tramways from 1,444,000 to 1,569,000 (8¼ per cent.). The total revenue amounted to £23,827, an increase of £3,695, but owing to heavy expenditure on repairs to plant the working expenes increased by £2,500 to a total of £13,191. The gross profit was £10,636, but after paying interest and sinking fund and special charges (£1,200) the net profit was £124. The cost of production had been reduced from 0·66d. to 0·64d. per unit.

Stepney (London).—The accounts of the electricity department for the year ended March 31 show capital expenditure £397,305 (increase £41,046). Provision has been made for repayment of £41,497 and £6,955 has been provided out of revenue to meet capital expenditure.

Revenue was £57,636 (compared with £52,266), working and general expenses were £33,528 (against £31,450), gross profit was £24,108 (£20,816 to which has to be added £351 (£361) minimum guarantees and interest from bankers and from investments, and net profit was £1,769 (£1,497). Fuel cost 0·436d. (0·470d.) per unit sold, works costs were 0·631d. (0·669d.), works and administrative costs 0·805d. (0·856d.), and total cost (including capital charges) 1·396d. (1·437d.), the average income being 1·409d. (1·458d.). 96,80800 (8,014,717) units were generated, 1,053,080 (1,027,427) purchased in bulk, 3,320,303 (3,027,894) sold for private lighting, 3,821,362 (3,388,215) for power and heating, 1,151,337 (1,165,372) for public lighting and 813,291 (427,693) bulk supply. The maximum supply into feeders was 4,091 kw. (3,669 kw.), and the dynamo capacity 7,720 kw. (5,720 kw.).

The report of the borough electrical engineer (Mr. W. C. P. Tapper) states that in February, 1910, the Council entered into contracts to the value of £32,852 for machinery, boilers, &c., to fill the available space in the existing buildings at Limehouse generating station and for sub-station plant for the Whitechapel station. The installation of the plant is nearing completion. During the transition of plant from Whitechapel to Stepney the bulk supply obtained from Poplar Council was of great assistance, 1,053,080 units having been purchased in 1910. The Limehouse plant comprises 6,000 kw. of turbine-driven generators and the Whitechapel plant 1,720 kw. of reciprocating plant. The maximum load at the generators (at Christmas) was 4,274 (increase 605 kw.), which showed a margin capacity of 1,446 kw. after allowing 2,000 kw. as spare. This margin should last until Christmas, 1913. The realisation of a profit of £1,769, instead of the estimated deficit, was due to the fact that the condensing plant at Limehouse was put into operation in October last, and since that time a saving of over £3,000 in cost of coal had been effected compared with the previous year's cost at Whitechapel. £1,671 was paid to the works department for destructor steam (=1,003,041 units), and (the report says) the very large reduction in cost of generation due to condensing at Limehouse renders it necessary that the charge of 0·4d. per unit at present made by the works department should be reconsidered. The total surplus since the inception of the undertaking is £25,887. The total number of (equivalent) 30-watt lamps connected is 447,862 (an increase of 62,597 compared with 74,134 in previous year). Nearly 250 consumers are taking restricted supplies (cut off between sunset and 7 p.m. in the winter) at 1d. per unit, over half a million units being taken on this system, and the advantage of this arrangement is seen in the improved load factor (24·32 per cent. compared with 22·9, which would have been the load factor if the restricted supplies had not been given). The set back in sales for private lighting due to the use of metallic filament lamps appears now to be arrested, an advance being recorded for 1910.

Sunderland.—The annual report of the electricity department was adopted by the Council on Wednesday.

Ald. Bruce, in moving the adoption of the report, said the output for the past year was 10,208,000 units, as compared with 7,000,800 units for the previous year. There was a net profit on the year's working of £1,189.

Swansea.—The total revenue of the electricity department for the year ended March 31 was £26,320.

Expenses were £13,542, leaving gross profit £12,778. 1s. 11d., an increase of £500 over 1909-10. After paying interest, sinking fund, &c., the net profit was £2,802, an increase of £80. The amount paid in rates was £1,638, against £799. The balance in hand is £8,062.

Tunbridge Wells.—The total revenue of the electricity department for the year ended March 31 was £13,991, including £10,094 from the sale of electricity, £2,793 from public lighting, £539 from meter rents and £274 for lighting Town Hall, &c.

The total expenses (£7.713) included £4,406 for generation, £788 distribution, £653 public lamp maintenance, £374 rent, rates and taxes, and £1,386 management. The gross profit was £6,277, and after paying £4,375 as dividends on and redemption of Corporation stock and £1,423 for interest on and repayment of mortgage loan there was a net profit of £479. The stock and loans authorised amount to £90,092, of which £38,500 has been repaid. 1,113,270 units were generated (against 1,078,018 in 1909-10) and 838,500 (831,136) were sold, of which 593,500 (578,025) were supplied to private consumers and 245,000 (253,111) to public lamps. The connections to the mains are equal to 75,521 30-watt lamps (against 70,681), and the total maximum supply demanded was 560 kw. (against 569 kw.).

In an interesting report by the borough electrical engineer (Mr. J. W. Beauchamp) it is stated that the units sold to private consumers showed an increase of 3·74 per cent. over 1909-10. In the previous year there was a decrease of 11 per cent., due to the rapid introduction of metal filament lamps, but the effect of the change has been stemmed by the very considerable amount of new business obtained. The cost of fuel per unit sold was reduced from 1d. to 0·8d., and the net works costs (generation plus distribution) was 1·49d. against 1·725d. In the distribution and public lighting departments a large amount of renovation and replacement of obsolete apparatus was effected out of revenue, to which account all new meters and replacements of obsolete patterns are also debited. Old type a.c. arc lamps are being replaced by high candle-power metal filament lamps with very satisfactory results. Several extensions to supply premises situated beyond the boundaries of the borough are now being made under the provisions of the Electric Lighting Act, 1909. New connections have been made amounting to 145 kw., of which a considerable portion represents heating and cooking apparatus and single-phase motors for driving machinery. The sales of energy for heating and occasional motors increased by 22 per cent., and for industrial motors by 105 per cent.

Wednesbury.—The annual report of the electricity department was adopted by the Council on Monday.

The Electricity Committee reported that there had been an increase of 92 consumers, and in the sale of current from 433,267 units to 634,356 units. The net profit was £583, and it was proposed to write £245 off the "free" wiring account and to allocate £300 to relief of rates. Extensions of the plant and mains at a cost of £2,250 were authorised.

York.—The accounts of the electricity supply and tramways departments for the year ended March 31 have been approved by the Council.

The total revenue of the electricity department for the year was £19,591 (against £14,629), and included £12,484 from sale of current to private consumers, £1,761 from public lighting, £4,465 from the tramways department and £811 from the rental motors, &c. The total expenses were £8,480 (against £6,095), and the gross profit was £11,111 (against £6,804). After paying interest on loans (£4,627) and sinking fund (£5,326) there was a net profit of £1,260. The capital expended is £131,372, an increase of £3,948 (due to expenditure on mains and motors for hiring). 2,536,389 units were generated (against 1,789,461) and 2,200,517 (1,438,700) sold, including 257,269 (245,456) for public lighting, 1,288,529 (1,093,235) to private consumers, 47,400 (50,000) by contract and 191,109 (140,546) for traction. There are 40 open and 69 enclosed type arcs and 92 incandescents for street lighting, and the total maximum supply demanded was 1,267 kw. (against 1,035 kw.).

The total revenue of the tramways department was £17,569 (9·2d. per car-mile), including £17,096 traffic receipts. The total expenses were £11,291 (5·91d. per car-mile), leaving a gross profit of £6,278. After paying interest (£3,394) and contributing £995 to sinking fund, the balance (£1,890) has been placed to reserve fund. The capital expended is £112,900, an increase of £37,646.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

Hammersmith (London) Borough Council invite tenders for supply of about 600 time switches suitable for controlling individual electric lamps for lighting side streets. The switches are required to deal with 1 ampere at a pressure of 120 volts single-phase a.c. 50 periods. Samples of switches tendered for should be addressed to the borough electrical engineer, Mr. G. G. Bell, 85, Fulham Palace-road, Hammersmith, W. Tenders to the town clerk, Mr. H. Thompson, by 4 p.m. Friday, June 30. See also an advertisement.

The Electricity Committee of Hull Corporation invite tenders for one year's supply of electric cables and for the supply of the two water-tube boilers required in connection with the extensions of plant at their Sculcoates-lane generating works. Forms of tender and specification from the city treasurer, Mr. T. G. Milner, and tenders, addressed to the Chairman of the Electricity Committee, Town Hall, Hull, must be delivered by noon of Monday, June 26. See also an advertisement.

Hull Education Committee require tenders by 10 a.m., June 20 for supply of electric fans and wiring and fitting for electric light at the new Sculcoates-lane school. Specification, from City Architect.

Hammersmith Council also invite tenders for supply of sundry wrought-iron flues. Specification and form of tender from the borough electrical engineer, Mr. G. G. Bell, and tenders to the town

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1911 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 24th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1911 Big Blue Book, making it the most complete work of the kind ever published.

clerk, Mr. H. Thompson, Town Hall, Hammersmith, W., by 4 p.m. Wednesday, June 21. See also an advertisement.

Tenders are invited for supply of lead-covered and vulcanised rubber-covered cable to the City of MELBOURNE. Specifications, tender form and conditions of tender from the agents for the City Council, Messrs. Mellwraith, McEacharn & Co. Proprietory (Ltd.), Bilbter-square-buildings, London, E.C., to whom tenders by noon Friday, July 7. See also an advertisement.

Tenders are invited for the supply of 150 miles insulated wire and 5 miles of telegraph cable to the Postmaster-General's Department in Victoria. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to July 19 for the supply of insulators, telephones, copper and iron wire to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W. See an advertisement.

The Secretary of H.M. OFFICE OF WORKS invites tenders for providing and erecting at the South Kensington generating station complete surface-condensing plant, capable of dealing with 15,000 lb. of steam per hour, together with the necessary gantry and stanchions. Forms of tender and further information may be obtained at H.M. Office of Works, Engineering Division, 55, Whitehall, London, S.W., Tenders by 11 a.m., June 30, to Secretary, Storey's Gate, London, S.W.

GOVAN Corporation require tenders by June 27 for supply and erection of steam, exhaust and water piping, boiler, mechanical stoker, coal bunkers, and cooling tower and for extension of h.t. switchboard. Specifications, &c., from the Burgh Electrical Engineer.

SWINDON Corporation require tenders by noon June 20 for the supply and erection of a 220-cell battery, an automatic reversible traction booster, a three-wire hand-regulated booster, and switchgear. Specifications, &c., from the Borough Electrical Engineer.

MANCHESTER Electricity Committee invite tenders for supply and erection of two water-tube boilers, superheaters, coal chutes, ash conveyors and fuel economisers. Tenders to Chairman of Committee, Town Hall, Manchester, by 27th inst.

IPSWICH Guardians require tenders by noon June 30 for alterations to switchboards and other electrical apparatus at the workhouse. Specifications, &c., from Mr. H. P. Girling, the Wharf, Maldon, Essex.

ROTHERHAM Corporation want tenders by July 8 for 12 months' supply of single vulcanised bitumen covered cable and electricity meters. Particulars from the Borough Electrical Engineer.

BIRMINGHAM Electric Supply Department require tenders by June 26 for 12 months' supply of electrical accessories, engineering and general stores, &c. Particulars from the City Electrical Engineer.

LONDON County Council require tenders by 11 a.m. July 4 for four electric traversers for car-sheds. Specification, &c., from the Clerk.

The Metropolitan Water and Sewerage Board, Albert-street, BRISBANE, Queensland, want tenders by noon Jan. 30 next for supply and erection, of one, two or three complete units, each consisting of power generating plant and pump or pumps to lift not less than 6,000,000 gallons per day. Particulars from the Secretary.

Tenders are invited up to July 25 for the supply of 12 sections of a branching multiple magneto lamp signalling switchboard, &c., or one automatic or semi-automatic switchboard, &c., to the Postmaster-General's Department, VICTORIA. Tender forms, &c., from 72, Victoria-street, London, S.W.

The Town Clerk, WANGANUI, N.Z., will receive tenders until July 12 for supply of generating plant, gas-producing plant and battery and booster for the Corporation tramways. Specification can be seen at 73, Basinghall-street, London, E.C. Local representation is necessary.

WELLINGTON (N.Z.) Corporation require tenders by 4 p.m. Aug. 24 for supply of a motor power wagon and accessories for the electric tramways department. Gonville and Castlecliff Tramway Board, Ridgway-street. WANGANUI (N.Z.) require tenders by 4 p.m. Aug. 14 for supply of overhead tramway material, feeders, &c. Conditions, &c., can be seen at 73, Basinghall-street, London, E.C. Representation in New Zealand is necessary.

The Chairman of the Board of Control, WINNIPEG (Canada), will receive tenders until 11 a.m. July 3 for supply and installation of a police patrol telegraph system.

NAPLES Municipal Authorities require tenders by July 9 for supply and installation of the following plant in connection with the supply of electric power to Naples from the river Volturno:

1. Tubing and accessories for harnessing the water at rate of 7,000 litres a second and for the fall of 190 meters; upset price 702,900 lire (£28,116.)

2. Machinery and apparatus for hydro-electric power station, transmission line (about 57 miles), and transforming station; upset price 1,000,000 lire (£40,000.)

Tenders to Presidente del Consiglio Generale dell' Ente Autonomo Volturno, Naples.

Manufacturers who are prepared to supply 600 km. (372 miles) copper wire 8 mm. dia. are invited to communicate with the Direzione dell' Ente Autonomo Volturno, Naples, who after two months from April 10 will send invitations to tender to firms whom they consider suitable.

Conditions of tender, &c. (in Italian) may be seen at 73, Basinghall-street, London, E.C.

The Secretary of the Works Department of the port of CADIZ will receive tenders until 5 p.m. June 20, for supply of four electric cranes. Particulars from the Public Works Department, Madrid.

Tenders will be received by Senor Alcalde, Casa Consistorial, VILLARROBLEDO (Spain) until June 26 for 10 years' supply of electric light for the town, and until June 30 for 25 years' supply of electric light to TORS (Zamora Province) Municipality.

Extension of Time.—The time for the receipt of tenders by the Egyptian Ministry of Public Works CAIRO, for an electric pumping installation (*see* p. 356 of our last issue) is extended to 10 a.m. June 24.

TENDERS RECEIVED AND ACCEPTED.

Salford Council has accepted the following tenders:—Hadfield's Steel Foundry Co., special tramway trackwork at £2,304; Berry Transformer Co., two transformers at £39. 10s. each; W. T. Glover & Co., for annual supply of single insulated cable, twin workshop flexible cable, rubber cable and bare rubber stranded wire cable at £2,000; Aubert, Grenier & Co. for multiple core cable.

Bristol Council has accepted the following tenders for annual supplies:—

Wm. Geipel & Co., are lamp carbons for open type lamps, £345. 15s.; Sloan Elec. Co., carbons for flame type lamps, £370. 11s. 4d.; Sykes & Sugden, joint boxes, £198. 17s. 1d.; British Westinghouse Co., watt-hour meters, £385. 15s.

Walsall Council has accepted the following tenders:—

British Westinghouse Co., h.t. switchgear for generating station; Johnson & Phillips, supply and fixing transformer at Bloxwich sub-station, and a design for illuminating the Council house for the Coronation; W. Kendrich & Sons, erection of Bloxwich electrical sub-station.

Wigan Council have accepted the following tenders for material for Coronation illuminations:—

General Electric Co., 1,500 yds. pixielight, 2,230 lamps, 125 gelatine lanterns, lgobes, &c.; W. T. Glover & Co. (lowest tender), for cable, £282. 10s. 9d. (Four tenders received, highest £302. 10s.)

Cheltenham Council have accepted the following tenders for annual supplies:—

British Thomson-Houston Co., meters, at 17s. 6d. each; W. Geipel & Co., open-type arc lamp carbons; Ship Carbons (Ltd.), flame carbons.

Ilford Urban Council have accepted the following tenders:—

Drake & Gorham, distribution switchboard and neutral board, £162. 15s.; Union Cable Co., feeder cable, £1,304. 8s. 10d.; Albion Clay Co., stoneware conduits, £312. 14s. 2d.

Digitized by Google

Barrow-in-Furness Council has accepted the tender of Edgar Allen & Co. for points and crossings at £372, and that of the Barrow Hematite Steel Co. for tram rails at £6. 15s. per ton and fishplates at £8. 15s. per ton.

Richmond (Surrey) Council have accepted the tender of Beard & Co. (Richmond) for the testing and maintenance of fire alarms at £52 per annum, for connecting up the system to the houses of new members of the fire brigade at £1. 10s. each and connecting up new residences of old members at 18s. 6d. each.

Ramsgate Council have accepted the tender of the local electric supply company for an electric motor and pump for the sewage works at £44. 16s.

Leyton Council received five tenders for Coronation illuminations at the two branch libraries, varying from £190 to £203, and the tender of Boston & Co. (at £200) was accepted.

St. Helen's Council have accepted the tender of Dick, Kerr & Co. for a 2,000 kw. turbo-generator, and that of the Mirrlees-Watson Co. for condensing plant.

Tunbridge Wells Council have placed an order with Jas. Keith & Blackman Co. for an electric fan, motor, &c., for the Town Hall at £75.

Stockport Council have accepted the tender of W. A. Shaw & Co. for wiring work at the baths.

Kendal Council have placed an order for a boiler (at £323) with the Yorkshire Boiler Co.

Bacup Council have accepted the tender of Ferranti Limited for two transformers, and that of the General Electric Co. for meters.

Canterbury Council have accepted the tender of E. J. Philpot & Son for wiring the public buildings for illumination at £50.

Northampton Council has placed an order with Dick, Kerr & Co. for two new tramcars at £555 each.

We have received a notification that the Felten & Guilleaume Fabrikelektrischer Kabel, Stahl und Kupferwerke A.G., the Kabelfabrik und Drahtindustrie A.G., the Oesterreichische Bergmann-Elektrizitätswerke Ges. and the Siemens & Halske Kabelwerk have been entrusted (by Franta Ludikar, of Prague) with the whole of the contract obtained by the last-mentioned firm for three years' requirements of lead-covered cable for Prague municipality.

BUSINESS NOTICES.

Mr. J. G. Lorrain, M.I.Mech.E., M.I.E.E., &c., consulting engineer and chartered patent agent, will remove to Staple Inn-buildings, Holborn, London, W.C., on 24th inst.

Messrs. Handcock & Dykes have removed from No. 1 to No. 11, Victoria-street, London, S.W. Telephone, "231 Vicotria"; telegrams, "Rheophore London."

It is announced that the partnership hitherto existing between Mr. A. E. Woodhouse and Mr. Edgar Jones (trading as the Woodhouse Steel Casing Co.), electrical engineers and manufacturers, has been dissolved, and the business hitherto carried on by the Woodhouse Steel Casing Co. has been transferred to the Woodhouse Steel Casing Co. (Ltd.).

The Electrical Apparatus Co. have appointed Mr. Thos. G. Travis, formerly of the British Westinghouse Co., to be their Lancashire and Yorkshire representative. The company state that their business in that territory has expanded very considerably during the last 12 months, and Mr. Travis will shortly open their Manchester office.

Thos. Percy Shillcock and John Harold Payne (trading as T. P. Shillcock & Co.), electrical engineers, 10, Gothic-arcade, Snow-hill, Birmingham, have dissolved partnership. Debts by Mr. Payne, who continues.

Notice to Coronation Illumination Contractors.—Messrs. Siemens Bros. Dynamo Works (Ltd.) are issuing a post card stating that their London stores, 39, Upper Thames-street, E.C., will be open until 11 p.m. on Tuesday, 20th, and all night on Wednesday, 21st inst. Telephone, 8,270 London Wall.

Patents Development.—The owner of British patent No. 18,043/1907 for "Process for the production of Metallic Deposits," desires to sell his patent rights or to grant licences. Particulars from Messrs. Day, Davies & Hunt, patent agents, 321, High Holborn, London, W.C.

The proprietor of patent No. 16,500 of 1907 for "Improvements relating to Electric Self-winding Clocks," desires to make arrangements for exploiting same in this country. Communications to Messrs. Haseltine, Lake & Co., patent agents and consulting engineers, 7 and 8, Southampton-buildings, Chancery-lane, London, W.C.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

Imports.—The following are official values of electrical machinery, material and apparatus imported into this country (*a*) during May, 1911, and (*b*) during the current year from Jan. 1 to May 31, with the increases or decreases compared with the corresponding periods of 1910:—

Electrical machinery (*a*) £79,380 (increase £27,887), (*b*) £461,578 (increase £228,496); telegraph and telephone cables (*a*) £40,808 (increase £32,450), (*b*) £162,425 (increase £101,146); telegraph and telephone apparatus (*a*) £12,107 (decrease £3,685), (*b*) £64,228 (decrease £10,450); other electrical wires and cables, rubber insulated (*a*) £5,423 (decrease £14,342), (*b*) £35,858 (decrease £33,134); with other insulations, (*a*) £2,492 (decrease £1,451), (*b*) £16,029 (increase £3,192); carbons (*a*) £10,435 (decrease £1,134), (*b*) £56,106 (decrease £1,754); glow lamps (*a*) £22,301 (decrease £32,555), (*b*) £138,508 (decrease £89,302); arc lamps and electric searchlights (*a*) £33 (decrease £115), (*b*) £597 (decrease £952); parts of arc lamps and searchlights (other than carbons), (*a*) £10,391 (increase £4,342), (*b*) £46,346 (increase £16,098); primary and secondary batteries (*a*) £3,948 (increase £541), (*b*) £19,893 (increase £2,645). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire (*a*) £121,356 (decrease £10,458), (*b*) £589,530 (decrease £3,002).

Exports.—The exports of electrical machinery, material, &c., (*a*) during May, 1911, and (*b*) during the current year from Jan. 1 to May 31, and the increases and decreases compared with the corresponding periods of 1910, are as follows:—

Electrical machinery (*a*) £156,332 (increase £50,117), (*b*) £698,307 (increase £129,594); telegraph and telephone cables (*a*) £56,013 (decrease £10,172), (*b*) £295,959 (decrease £574,362); telegraph and telephone apparatus (*a*) £15,188 (increase £1,805), (*b*) £109,537 (increase £43,674); other electrical wires and cables, rubber insulated (*a*) £30,930 (decrease £4,024), (*b*) £166,866 (decrease £5,514); with other insulations (*a*) £34,156 (decrease £222), (*b*) £166,453 (increase £52,944); carbons, (*a*) £1,594 (increase £371), (*b*) £8,398 (increase £985); glow lamps (*a*) £13,192 (increase £3,504), (*b*) £65,390 (increase £13,895); arc lamps and searchlights (*a*) £1,923 (increase £1,079), (*b*) £7,736 (decrease £30); parts of arc lamps and searchlights (other than carbons) (*a*) £1,540 (increase £509), (*b*) £6,276 (increase £565); primary and secondary batteries (*a*) £10,055 (increase £2,308), (*b*) £60,079 (increase £18,762). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire, (*a*) £215,466 (increase £8,917), (*b*) £1,118,146 (decrease £406,482).

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*NOTE.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

April 28, 1911.

10,290 KÖRTING & MATHIESEN AKT.-GES. Electric arc lamps for alternating current. (Addition to 26,706/09. Convention date, 30/4/10. Germany.)*
10,303 HANSEN. Metal filaments for electric incandescent lamps.
10,309 BENTALL, BINGHAM & GRAY. Electro-magnetically controlled throttle valve.
10,313 BARKER. Incandescent electric lamps.
10,315 RAWLINGS & NICHOLSON. Distribution of electrical energy.
10,316 RAWLINGS. Electric lighting systems and lamp holders and connecting devices for use in connection therewith, or on ordinary systems.
10,317 RAWLINGS & NICHOLSON. Distribution or supply of electrical energy.*
10,318 RAWLINGS. Electrical switsches or distributing devices.
10,341 SIEMENS BROS. & CO. (Siemens & Halske Akt.-Ges., Germany.) Subscribers' instruments for automatic telephones.*
10,342 SIEMENS BROS. DYNAMO WORKS. (Siemens-Schuckertwerke G.m.b.H., Germany.) Maintaining a constant speed in direct-current motors.*
10,358 SIEMENS BROS. & CO. & MARECHAL. Electric incandescence lamps.
10,363 REGAL. Electric jacquard apparatus. (Convention date, 17/5/10, Austria.)*
10,364 BROWN. Controllers for electric motors.

April 29, 1911.

10,375 WINTER. Electric lamp shades, screens or the like.
10,433 HUBERS. (Berliner Siriuslampen-Vertriebsges. m.b.H., Germany.). Incandescent electric lamps and the mounting of same for illumination advertisement.
10,434 HUBERS. (Berliner Siriuslampen-Vertriebsges. m.b.H., Germany.) Fastening incandescent electric lamps to sheet-metal discs.
10,435 HUBERS. (Berliner Siriuslampen-Vertriebsges m.b.H., Germany.) Holders for electric incandescent lamps.

May 1, 1911.

10,472 WILDEY & MERRETT. Electrically lighted display boards.
10,486 BARTON. Perforator for electric telegraphs.
10,527 DOWNTON & KIBBLEWHITE. Holders for electric incandescent lamps.*
10,545 ZICKEL. Electric shutter indicators. (Addition to 26,502/08. Convention date, 2/5/10, Germany.)*
10,549 B.T.-H. Co. (G.E. Co., U.S.) Electric heating devices.
10,550 & 10,551 ELEKTROMOTOREN-WERKE HERMANN GRADENWITZ. Remote control systems for electrically-driven vehicles. (Convention date, 27/5/10 and 22/9/10, Germany.) (Addition to 10,550/11.)*

May 2, 1911.

10,624 Mitchell. Road switches for surface contact electric traction systems.
10,639 Galletti. Production of quenched electrical spark discharges. (Convention date, 3/5/10. Italy.)*
10,650 Lesty. Laying and picking up field telephone lines and the like.
10,652 Lofquist. Automatic circuit breaker.*
10,664 Brown. Variable resistance contact devices for electrical transmission purposes.

May 3, 1911.

10,668 Heenan. Masts for wireless telegraphic and other purposes.
10,689 Mountson. Electric meters of the electrolytic type.
10,694 Brownlee. Device for protecting the body from electric currents.
10,701 J. Halden & Co. & Watts. Electric photographic printing or copying machines.*
10,747 W. T. Henley's Telegraph Works Co. & Judge. Electric switches.
10,758 Newton. Dynamo-electric machines. (Addition to 15,423/10.)
10,765 Quain. Electric heaters.
10,767 Frisali & Visconti. Electrical heating apparatus.

May 4, 1911.

10,785 Spence. Differential electric rope gear.
10,792 Schott & Gen. Electrolytically measuring electricity. (Convention date, 23/5/10. Germany.)*
10,804 Shire. Leverless contact breaker for high-tension magnetos.
10,816 Chamberlain & Hookham & James. Electricity motor meters.*
10,824 Siemens Bros. & Co. (Siemens & Halske Akt.-Ges., Germany.) Alternating current block circuits.*
10,841 Lake. (U.S. Light & Heating Co., U.S.) Automatic electric switches.*
10,845 Mareyat. Electric lifts.
10,856 Kramer & Kapp. Resonating relays.
10,857 Kramer. Inductive wireless telegraphic installations.
10,858 Pearson, Zsvetaeff & Tistchenko. Electric furnaces.*
10,859 Poersche & Achenbach. Electrodes for secondary galvanic cells. (Convention date, 27/1/11, Germany.)*

May 5, 1911.

10,967 McCaffery & Klyne. Electrically-operated time switches or time mechanisms.
10,971 Bastian, Newman & London Electrical Trading Co. Preventing overheating in electrically heated boilers and the like.
10,986 Koeting & Mathiesen Akt.-Ges. Rainproof ventilator for arc lamps. (Convention date, 6/5/10. Germany.)*
10,992 Dicker. (Automatic Electric Co., U.S.) Telephone systems.

May 6, 1911.

11,048 Nell. Feedine low-voltage lamps and other low-voltage electrical devices in a high-voltage net. (Convention date, 7/7/10. France.)*
11,068 Lucas & Eppinton. Electric lamps for motor vehicles and other purposes.
11,070 Ingram. Transmitting news, reports, and the like by telegraphic or similar means.
11,075 Dawson & Buckham. Electrical apparatus for transmitting and receiving speech.

SPECIFICATIONS PUBLISHED.

1910 Specifications.

10,738 Godfree. Electro-mechanical selector. (28/5/09.)
10,758 Liddle. Electric motor-driven capstans.
10,776 Adams Mfg. Co. (Cutler Hammer Mfg. Co.) Electric circuit controllers.
10,864 Harrison. Manufacture of incandescent electric lamps.
10,870 Von Zweigbergk. Dynamo-electric machines.
10,903 Murray. System of heating interiors by means of electric radiators.
10,925 Veritys, Ltd., & Pipkin. Electrically-heated soldering iron or tool.
11,037 Mines & Rail-less Electric Traction Co. Trolley poles for electric traction systems.
11,070 Seward, Von Kugelin & Von Bidder. Electrolytic production of light metals, and particularly sodium. (10/5/09.)
11,091 Crossley & Hamer. Cord-grips for incandescent lamp holders.
11,[illegible] Kitsee. Metallic filaments for electric lamps.
11,[illegible] Walters. Stable arc lamps.
11,[illegible] Pressler. Automatic polarisation of fluid condensers in an electric welding apparatus. (Addition to 14,859/10.)
11,[illegible] Siemens Bros. Dynamo Works. (Siemens Schuckertwerke Ges.) Working electric motor and like controllers.
11,[illegible] Mines & Rail-less Electric Traction Co. Electric traction systems.
11,[illegible] Price. Switches for working with dynamos, accumulators, and the like. (6/11/10.)
11,[illegible] Waterhouse. Ceiling roses for electric light pendant fittings and the like.
11,[illegible] Salzer. Igniting magnetos of internal-combustion engines. (20/9/09.)
11,[illegible] Roberts & Prescott. Attachment devices for the shades of electric lamps and the like. (18/10/10.)
11,[illegible] Hinson & Johnson. Telephonic apparatus.
11,[illegible] Swangeon. Incandescence electric lamps. (18/9/09.)
11,[illegible] Deeke & Imperial Lamp Works (Brimsdown). Incandescent electric lamps.
24,123 Western Electric Co. (Western Electric Co.) Suspended hygroscopic shield for suspended electrical conductors.
24,[illegible] Marchant. Telephonic transmitters.
24,[illegible] Wicker. Waterproof protector for electric lamps.
24,[illegible] Mitchell & Duggeon. Section insulators for overhead wires and cables of tramway, railway, and like systems.
24,[illegible] Block. Trolleys or collectors for electric cars.
24,[illegible] Brown & Schneider. Galvanic gas cells.
24,[illegible] Aktiengesellschaft Elektricitats-Ges. Compensation of polyphase commutating dynamo-electric machines. (16/11/09.)
24,[illegible] Block. Dynamo-electric machines.
24,[illegible] Prestwich. Means for electrically igniting miners' safety lamps.
24,[illegible] Elektromechanische Werke Ges. Rectification of alternating electric currents and devices for use therein. (22/11/09.)
24,[illegible] Fauli. Overhead systems for transmitting electricity. (21/12/09.)
24,[illegible] Schneider. Verifying the operation of apparatus for distant electrical transmission and control of operations.
24,[illegible] Crompton & Co., Macfarlane, Burge & Williams. Means for regulating electrically-operated driving systems.
24,[illegible] Siemens Bros. Dynamo Works. (Siemens Schuckertwerke Ges.). Regulation of alternating current generators working in parallel.
24,[illegible] Siemens Bros. & Co. (Siemens & Halske Akt.-Ges.). Telephone exchange circuits.

1911 Specification.

[illegible] Hesse & Schultze. Electric traction on elevated cable tracks. (Divided application on 12,843/10. 26/5.)
[illegible] Pilé. Electric Storage Cells or Batteries.
[illegible] Brown & Trafagna. Switches adapted for operating the electric lamps of illuminated signs and the like.
[illegible] Aktiengesellschaft Elektricitats Ges. Electricity meter which indicates the consumption above a certain energy. (9/2/10.)
[illegible] Adams Mfg. Co. (Cutler Hammer Mfg. Co.) Electro-magnetic relay devices. (Divided application on 7,332/10. 25/4.)
[illegible] Fletcher. Magneto-electric machines.
[illegible] Fletcher. Magneto-electric machines.
[illegible] Siemens & Halske Akt.-Ges. Automatic telephone exchange circuits. (1/3/10.)
[illegible] H. Aron Elektrizitatszahlerfabrik Ges. Prepayment electric meters. (4/4/10.)
[illegible] Kjellman & Pentelec Welding Patents. Electric transformers. (Divided application on 10,694/10. 30/4.)
[illegible] Siemens Bros. & Co. (Siemens & Halske Akt.-Ges.). Electric order signalling apparatus. (Addition to 19,684/09.)

COMPANIES' MEETINGS AND REPORTS.

Peel-Conner Telephone Works (Ltd.)

The first ordinary general meeting of this company took place on Monday, Mr. Hugo Hirst presiding.

The SECRETARY (Mr. P. P. Kipping) having read the notice convening the meeting and the auditor's report,

The CHAIRMAN said: It may be expected of me that, at this first meeting of shareholders of the Peel-Conner Telephone Works, I should say a few words as to the inception of the company, its past year's trading, &c. This company was started because your directors realised that there is to be a big telephone business in this country, in the colonies and in foreign countries. The development of the common battery system makes it certain that much of the existing exchange plants within a few years may have to be scrapped, and the improved service obtained by the common battery system will make telephony much more popular. Your directors (I should say, your present directors) felt that, owing to the monopoly enjoyed by the National Telephone Co., and under the practice they indulged in of buying their plant principally from foreign houses, it was not possible to establish an industry in this country earlier. But on the Post Office taking over the management, with the desire of buying its supplies from home manufacturers, and desirous of taking full advantage of the more modern system of common battery exchanges, they let it be known that they would prefer to confine their purchases to British products, if a sufficient and healthy competition of home producers could be created. Relying on our ability to manage works and men, and assisted by one of the foremost telephone experts, now our managing director, Mr. M. S. Conner, we decided to enter the field. The work during the first financial period already justifies our action. It would scarcely have been surprising to me if I had to present a balance-sheet which would not have enabled us to declare a dividend this year. At the starting of new works one has to reckon with so many problematical figures and facts. We have not followed others. We have been original right through.

Turning to the balance-sheet, the only figures which require comment are: (1) On the debit side, loans from bankers, (2) on the credit side, cash in hand and stock in hand. For the reason above explained, it has been impossible to complete all orders obtained during the financial year under review, and, as a result, our stock in hand and the work in progress amounts to some £30,000 to £40,000 of finished or nearly finished work for contracts which are being executed in this financial year, and the profit on the manufacture of this large amount of stock will show in the coming year's work. Our capital of £100,000 was not sufficient to deal with such items of stock, and in consequence we relied on our bankers to assist us to complete these contracts. After expressing his views on the subject of the ability of the Post Office to efficiently carry on the telephone business of the State, Mr. Hirst said there were ways by which the telephone service could be extended. Why should not the Post Office bring their mains to the houses and let duly qualified manufacturers and engineers instal private houses, factories, offices and the like with up-to-date telephone service at defined rates and on certain conditions and tests, exactly as electricity undertakings do? This would mean a staff of inspectors in the service of the G.P.O., but under such a method of extending the telephone business the Post Office would have at its command the service and enterprise of the whole of the electrical trade for getting subscribers. This was his own suggestion, but when the time came many more or less contentious schemes were conceivable. He now moved the adoption of the report and accounts.

Mr. JAS. FRASER seconded the motion and congratulated the shareholders on the first balance-sheet. He felt confident that the next would be much better.

The resolution was carried.

The retiring director (Mr. E. G. Byng) was re-elected, the auditor (Mr. C. S. Nicholson) was re-appointed, and the proceedings closed with a vote of thanks.

Digitized by Google

ARON ELECTRICITY METER (LTD.)—For the year ended March 31 the profit and loss account, after providing for general charges and depreciation, shows a net profit of £27,520. 17s. 6d., making, with £5,353. 11s. 2d. brought forward, a total available profit of £32,874. 8s. 8d. Out of this the directors distributed in December a preference dividend of 3 per cent., absorbing £3,746. 17s. 7d., leaving £29,127. 11s. 1d. The directors now recommend payment of the balance 3 per cent. on the preference shares (absorbing £3,746. 17s. 7d.), a dividend of 6 per cent. on the ordinary shares (absorbing £7,500), and to transfer £5,000 to reserve towards goodwill and patents, leaving £12,880. 13s. 6d., out of which it is proposed to appropriate £7,000 towards writing off expenses of debenture issue of 1911, and to carry forward £5,880. 13s. 6d. The past year's trading has been most satisfactory, the sales having again exceeded those of any previous year. The factories have been fully employed and the necessary extensions to cope with the increased business have been carried out. The taximeter business is still progressing satisfactorily in England, Belgium and Austria.

HAVANA ELECTRIC RAILWAY CO.—The report for 1910 states that the gross earnings were $2,656,979, operating expenses $1,365,640, leaving $1,291,338. Fixed charges and taxes amounted to $448,128, leaving $843,209. Adjustments amounted to $1,549, and available surplus earnings were $844,759. Dividends were paid during the year of 6 per cent. on preferred ($300,000) and 6 per cent. on common shares ($447,821), leaving $1,114,913. after taking into account the amount brought forward from 1909.

WESTINGHOUSE ELECTRIC & MFG. CO.—The report of this company and its subsidiaries for the year ended March 31 states that the gross earnings were $38,119,000, an increase of nearly $9,000,000 over the preceding year. The net manufacturing profits are $5,609,000, making, with other income ($1,515,000) a total net income of $7,124,000. Deducting interest and other charges the surplus is $4,881,000. The surplus on March 31, 1910, was $5,669,000, which was increased by various items of profit throughout the year to $6,349,000. Adding net income for the year the surplus amounted to $11,230,000. Against this there have been charged dividends of preferred stock for year at rate of 7 per cent. per annum, plus remaining balance of dividends accumulated but unpaid in previous years ($630,000): in adjustment of account property and plant $1,193,000; to reserve for notes and accounts receivable $590,000; depreciation of investments $2,753,000. This leaves a surplus of $5,964,000.

NEW COMPANIES, MORTGAGES AND CHARGES.

NEW COMPANIES.

BENTINCK MOTOR SUPPLY CO. (LTD.) (116,155.)—Reg. June 1, capital £50,000 in £1 shares, to carry on the business of proprietors of and dealers in motor cabs, cars, &c., manufacturers of engines, dynamos, accumulators, magnetos, wheels, tyres, lamps, &c. Private company. First directors are S. Brooks (governing director and chairman), J. H. Smith and J. Nuttall. Reg. office: care of C. Lord, 13, Spring-gardens, Manchester.

FOREST-WEY TRUST CO. (LTD.) (116,161.)—Reg. June 1, capital £20,000 in £1 shares, to promote, contract, purchase, lease, or otherwise acquire, equip, work, maintain and operate railways and tramways in the U.S.A. or elsewhere and to carry on the business of rolling stock manufacturers, engineers, &c. Private company. First directors are J. Wayman and G. F. Thomson. Reg. office: 31, Lombard-street, E.C.

JACOB WHITE & CO. (LTD.) (116,217).—Reg. June 3, capital £2,000 in £1 shares, to carry on the business of electricians, manufacturers of and dealers in accessories, fittings and supplies, lighting engineers, electrical contractors, &c. Private company. First directors T. Jacob and E. W. White (both permanent). Reg. office, King's House, King-street, London, E.C.

KJELLBERG SYND. (LTD.) (116,140.)—Reg. May 31, capital £130 in £1 shares, to work and turn to account in the U.K. and colonies an invention for improvements in electric welding or soldering and for electric switches and to adopt an agreement with the Jektriska Svetsnings Aktiebolaget. Private company. First directors, G. T. H. Davidson, R. S. Prinsep, G. H. Hannay, E. G. Thormadlon, T. M. Aitken and J. B. Hamilton.

MOSCOW METROPOLITAN SYND. (LTD.) (116,059.)—Reg. May 26, capital £20,000 in £1 shares, to acquire concessions and rights, to construct or acquire any railway or tramways in Moscow or elsewhere and to equip, maintain and work same by electricity or other power, &c. Private company.

MORTGAGES AND CHARGES.

ARC LAMPS (LTD.) (70,795).—A memorandum of satisfaction in full on 27th May, of debentures dated 18th Dec., 1908, securing £4,000, has been filed.

DELHI ELECTRIC TRAMWAYS & LIGHTING CO. (LTD.)—Issue on May 22 of £600 bearer debentures, part of a series of which particulars already filed.

ENGINEERING & ARC LAMPS (LTD.)—Particulars of £6,000 debentures created 26th May, have been filed, amount of present issue being £5,500. Property charged: Co.'s undertaking and property, present and future, including uncalled capital. No trustees.

LONDON TELEGRAPH TRAINING COLLEGE (LTD.)—Particulars of £400 debentures, created 25th May, have been filed, amount of present issue being £300. Property charged: Co.'s undertaking and property, present and future. No trustees. A memorandum of satisfaction in full on 29th May of debenture dated 24th March, 1909, securing £100, has also been filed.

ALBY UNITED CARBIDE FACTORIES (LTD.) In a circular issued by the directors it is stated that the agreement entered into with the other European carbide manufacturers has been working satisfactorily and all contracts made at low rates prior to the arrangement have been executed. The price of carbide delivered since April 1 has been at an advance of about £2 per ton over that ruling during the previous year. The profits for the 12 months ending June 30 will, it is estimated, show an advance of about 40 per cent. The business of the North-Western Cyanamide Co. (in which they are largely interested) is progressing satisfactorily, and the plant is working to its fullest capacity and producing the maximum amount of cyanamide for which it was designed.

CHADBURN'S (SHIP) TELEGRAPH CO. (LTD.)—The directors recommend a dividend of 5 per cent. on the ordinary shares, making 8 per cent. for the past year.

CITY OF LONDON ELECTRIC LIGHTING CO. (LTD.)—The transfer books and register of holders of the 5 per cent. first and 4½ per cent. second debenture stock of this company will be closed from 17th to 30th inst., inclusive.

GWYNNES (LTD.)—The accounts for the year ended Jan. 31, 1911, show, after deducting debenture interest and allowing £3,067 for depreciation on plant, &c., a debit balance of £7,432.

MANILA ELECTRIC RAILROAD & LIGHTING CO.—A dividend of 1¼ per cent. for the quarter ending June 30 has been declared, payable in New York.

METALITE (LTD.)—The following gentlemen have been added to the Board of this company: The Hon. Sir Cornthwaite H. Rason, Kt. (ex-Premier West Australia), Mr. Walter Bernard Hopkins (director of A. Darracq & Co.), and Mr. William Stewart.

NATIONAL TELEPHONE CO. (LTD.)—The transfer books of the 3½ per cent. and 4 per cent. debenture stocks will be closed from 17th to 30th inst. inclusive, for the preparation of warrants for interest due July 1.

PROVINCIAL TRAMWAYS CO.—The directors have declared an interim dividend of 8d. per share.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed June 29 a special settling day in 125,000 £1 fully-paid vendors' shares of the *Juga (Nigeria) Tin & Power Co. (Ltd.)* The Committee have been asked to grant a quotation to 500,000 £10 fully-paid shares of the *Underground Electric Railways Co. of London (Ltd.)* (special application).

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON (LTD.)—A circular has been issued to the shareholders and to the holders of the Six per Cent. Income Bonds stating that the Lot's-road power house is now leased to the London Electric Underground and Metropolitan District Railway Companies as tenants in common for 999 years. It is provided each of the two companies being liable for and paying a moiety of the rent as part of its working expenses, the moiety attributable to each railway company being payable out of its revenues in priority to the interest on its present or future debentures and debenture stock. Under the present contracts for the supply of electrical energy to the railway companies the price paid for such energy includes a contribution to a depreciation fund which was established under the contracts. This fund at June 30, 1911, amounts to approximately £176,900, and is only applicable to payments for repairs and renewals of the generating station in so far as they are properly chargeable against depreciation. It is proposed that the price for the generating station undertaking should be £2,200,000 of power house rent-charge stock at par, or the nett proceeds thereof, and carrying a fixed perpetual dividend at the rate of 4 per cent. per annum. It is proposed that the sale and lease shall take effect on July 1, 1911, and that the dividend on the power house rent-charge stock shall commence to accrue on the same date. It is proposed to apply the balance of the purchase price remaining after payment of expenses incident to sale, first in redemption of the entire issue of £1,000,000 of first power house debentures now charged on the generating station undertaking, and then towards the redemption of the 4½ per cent. bonds of 1933 of the Company. The sale and lease of the undertaking to the two railway companies are not to take effect until the purchase price and conditions of sale and purchase and the terms and conditions of the lease have been duly approved by general meetings of the interests concerned.

NOTES.

Imperial Inter-Communication.

From the official report of the proceedings before the Imperial Conference on Thursday last week, it would appear that an interesting discussion arose on the allied subjects of telegraph cable rates, cable facilities, and wireless telegraphic communication. On the first point Sir Joseph Ward (representing New Zealand) introduced a motion asking for increased facilities for inter-communication between Great Britain and her Dependencies by means of reduced cable rates throughout the Empire, agreeing that much had been already accomplished in this direction, but arguing that more remained to be done. The Postmaster-General (the Right Hon. H. L. Samuel), in expressing the British Government's sympathy with this proposal, pointed out that the result of representations to the cable companies had been the important reduction of 50 per cent. in plain-letter messages, and it was probable that there would shortly be announced a further reduction in the charge per word for Press messages. He further indicated that an attempt would be made to effect some Governmental control over cable rates, the companies receiving due security against any abuse of such powers by an appeal to the Railway and Canal Commission. Sir Wilfrid Laurier and the Hon. A. Fisher both agreed that these were solid concessions, but the Hon. G. F. Pearce objected that, while the various Colonial Governments were prepared to bring about reductions forcibly, even if a loss resulted, the Railway and Canal Commission would view the matter from the point of view of the operating companies earning a profit on their work. While admitting that this might be an improvement, it was not the full result desired by the Governments concerned.

To the man in the street this will appear a carping criticism, and it certainly seems to require some further explanation from Mr. Pearce as to what basis in particular he would suggest on which the vast businesses of the cable companies with their Governmental ramifications should be conducted. The feature of many of these discussions is the airing of vague proposals and suggestions without any indication of how the cost is to be met, or what is to be done to ensure that no injustice shall be meted out to those who have placed their money in submarine telegraph cable enterprise. Non-practical views, expressed before Chambers of Commerce and other aggregations of traders, ever on the alert for their own advantage without regard to the justice of the case, are all very well, but when subjects involving millions of the British public's money are discussed before the Imperial Conference, something more tangible, some facts and figures bearing upon the questions, would be more to the point; and we venture to say that any really practicable proposal emanating from the Imperial Conference would receive the fullest consideration from those responsible for the conduct of telegraph cable enterprise. We think it will be agreed that a really practical proposal has yet to be submitted.

The Hon. G. F. Pearce was responsible, at the same meeting of the Conference, for a resolution recommending the "Nationalisation of the Atlantic Cable." Mr. Pearce did not support this resolution by any really practical suggestions, and no information was vouchsafed as to what would happen if the Atlantic cables were "nationalised." What is the present nationality of the Atlantic cables? And what is the attitude of the owners of the Atlantic cables in regard to the question? The laying of an additional Atlantic cable for some of the purposes set out by Mr.

Digitized by Google

PEARCE is, of course, a proposal whose financial results can be fairly estimated. So far as the proposal resolves itself into a question of expenditure of public money it is a simple one, but with the experience already gained with the Pacific cable the venture is one that is not to be lightly undertaken, at any rate so far as the Mother Country is concerned. We take it there is nothing to prevent the Australian Commonwealth, assisted by New Zealand and Canada, laying such a cable, but why the United Kingdom should be called upon to find a large sum of money for such an enterprise it is difficult to understand. The POST-MASTER-GENERAL had an easy task in shelving the question by means of a resolution given on another page of our present issue, where also a report of the "wireless" proposals of the Government is set out.

British Electric Traction.

APART from the interest which always appertains to the annual reports of large industrial undertakings, there is a special interest in the fifteenth annual statement of the directors of the British Electric Traction Co., in that the report seems to indicate a somewhat improved position in electric traction matters. Passing over the intimation that Sir CHARLES RIVERS WILSON, who has presided over the directorate of the Company from its inception in October, 1896, is about to retire from the chairmanship and is to be succeeded by Mr. E. GARCKE, whose strenuous work for the Company all associated with electrical matters fully realise, the views that Sir CHARLES presented to the meeting of shareholders last week contain many instructive details which, although not altogether new to our readers, very well bear repetition. The difficulties which the Company has either overcome or is suffering from are certainly numerous, and they cannot be re-stated too emphatically. They relate particularly to the trouble which must accompany competition with rate-aided rivals. We know from the reports that reach us from some of the great municipal electric tramway undertakings that the extremely low fares which predominate in many districts, the preference given to the often well-to-do and always much-considered "working man," have lowered the remunerative operation of tramway enterprise to its limit, in some cases resulting in loss. This result has come about in spite of the specially favourable terms upon which money can be borrowed on the security of the rates, of the advantages that municipal enterprises enjoy of being their own masters, in being the road authority, and in having a regular demand from local investors for their stock as investments, in having the call of the labour market in great measure, and otherwise. All this goes to show how necessary it is that sound business principles should actuate all classes of commercial enterprise. We do not think Sir CHARLES failed in his effort to show that the B.E.T. had not always been generously treated in the course of the negotiations in which, from the nature of its business, the Company has had to engage. Perhaps, however, special interest will be taken by electrical men in the chairman's very definite statement that the directors have decided to spend no more money in the extension of their enterprise unless and until they can secure better treatment. We can but hope that the clouds which hover over the Company's extensive and important undertaking will speedily pass away, and that the B.E.T. will once again become a profitable investment.

Edinburgh Theatre Fire.

THE public enquiry into the fire at the Empire Theatre, Edinburgh, which occurred on May 9th, has now been concluded; and the jury have returned their verdict (an abstract of which is given on another page of this issue). The evidence brings out two points very clearly; one, that the permanent electrical installation at the theatre was in no wise at fault, and the other, that the faulty construction of Lafayette's properties was at the bottom of the whole unfortunate business. The jury's verdict, therefore, seems rather beside the point. They simply recommend that theatres should be safely constructed and that more frequent examinations should be made of electric lights and water hydrants. This is, of course, all very well as far as it goes, but more important still is the examination of the artistes' own properties. In Lafayette's case these were extensive and included a complete electrical installation. Now it seems certain that it was among these properties that the fire originated. Assuming, as was stated in the evidence, that some of the joints were faulty, the advantage of inspecting merely the theatre installation is not very evident. Therefore, we think that more attention might be paid to the way in which the artistes' own installations are carried out, and that severe restrictions should be laid on the use of inflammable material for such purposes. Marking scenery as fireproof does not necessarily make it so, and this is a point that might be looked to. Further, though performances such as Lafayette gave may be very fine, is not the danger inseparable from carrying them out sufficient to render them illegal?

The I.M.E.A. at Brighton.

THE annual Convention of the I.M.E.A. which opens at Brighton on Tuesday next will be the first ever held wholly at the seaside. This, coupled with the fact that Mr. CHRISTIE is a popular President, should ensure a record attendance of members, even in spite of the distance from the North and the Midlands. The programme of meetings has already been published, but we reproduce it again in this issue for the convenience of our readers. The papers down for reading should promote a healthy and interesting discussion, particularly those on the internal combustion engine. Following the excellent precedent established last year at Glasgow, Thursday morning will be given over entirely to discussions. The subjects chosen, "The Purchase of Fuel" and "Street and Shop Front Lighting," embrace matters of considerable importance to station engineers, and we look for some interesting figures in the discussion on the latter. We are pleased to see in this year's programme a minimum of "official" functions. The municipalities in which the Convention is held always like to do honour to the members attending, but a plethora of public luncheons, &c., occupies too much of the time which engineers prefer to have at their own disposal. By confining its hospitality to a single conversazione Brighton has established a useful precedent, and one which we hope

Digitized by Google

will be followed by other towns in future. In another part of this issue we publish two articles on the Southwick power house of the Brighton Corporation and details of some of the large consumers who are connected to the supply mains. We shall give a full report of the proceedings up to Thursday night in next week's number, which will be available on Friday to members at the Convention.

Electrification of the Boston Railways.—According to "Engineering News," one of the schemes for electrifying all railways entering Boston, a subject which has been much discussed recently, is likely to be favoured by the Massachusetts Legislature. The Committee on Railroads and Metropolitan Affairs on May 25th voted for a measure which provides that all the standard-gauge railways within the metropolitan district shall be electrified in such a manner and in such order as the Board of Railroad Commissioners may determine. The railways are to file plans and specifications for electrification with the Railroad Commission before September 1, 1912. The Commission will determine the extent to which public necessity demands electrification, and will also fix a date for beginning the work.

"The Production of Characteristic Röntgen Radiations." In a Paper on this subject, read before the Royal Society, Mr. R. Whiddington stated that a characteristic radiation could usually be excited only when the velocity of the cathode rays using the X-ray tube supplying the primary rays exceeded a certain value depending on the radiator. The value of this critical speed v_c had been accurately determined for the radiators Cr, Fe, Ni, Cu, Zn, Se; that for Al had been given in a previous Paper. It appeared that for the radiators studied v_c was proportional to the atomic weight of the emitting element, being very nearly 10^8 times the atomic weight. The potentials corresponding to these velocities ranged between 1,320 volts and 15,400 volts. An interesting result obtained during the course of the investigation was that the energy emitted in the form of Röntgen radiation by a cathode particle when suddenly stopped was proportional to the fourth power of its velocity.

Inspection of High-Tension Oil Switches.—We take the following note on this subject from the "Electric Railway Journal." In the regular inspection of the transmission lines, which is the price of continuous service, it is important not to overlook the periodical examination of high-tension oil switches, particularly with regard to ascertaining the character of the oil and the condition of the contacts and terminals. The frequency of the inspection may properly depend on the use of the switches and the voltage, but, in any event, an annual overhauling, in which the contacts are tested and cleaned and, if necessary, the oil is renewed, is essential to the best results. Some companies may go so far as to keep monthly records of the number of times the switches are operated and establish a system of inspection on such a basis. In a representative case the practice is to test the oil weekly in all oil switches by taking out a sample and measuring its dielectric strength with a spark gap of from 0·15 in. to 0·30 in., and also to make this test on any switch immediately after it has been opened on short-circuit or through other trouble. A series of tests made on a sample taken from one switch which had opened a severe short-circuit showed very low resistance at first, but the resistance gradually increased for 48 hours, when it had come back practically to normal. The reduction in dielectric strength was doubtless due to the free carbon which was formed in the oil by the arc at the time of the rupture and which finally settled at the bottom. The importance of filtering the oil as soon as possible after a break of violent character was thus clearly indicated.

Cable Interruptions.

	Date of Interruption
Assab—Perim	July 8, 1909
Malta—Trinoli	April 20, 1910
Latakia—Palura	May 26, 1910

The Prevention of Earthing by Climatic Conditions.—According to the "Electrical World," the salt, wet air encountered at Galveston, Texas, so thoroughly permeates all buildings with conducting moisture that it is impossible to earth the secondaries of transformers on account of the painful shocks given from the brass socket shells or other metal parts which make contact with the unearthed side of the line. Buildings of wood, brick or concrete become so conducting after a brief exposure to the climate of this semi-tropical island that even when standing on carpeted floors on upper storeys one finds it impossible to touch any live conductor at ordinary lighting voltages. The capacity leakage effect, even from unearthed secondaries, in many cases proves unpleasant. Being an advocate of earthed secondaries elsewhere, when Mr. Fred M. Lege, Jr., the present manager of the Brush Electric Lighting & Power Co., first came to Galveston several years ago, he immediately took precautions to see that his own house service was properly earthed. Painful shocks at once became manifest from various sockets and switches, and members of the family and servants soon grew so fearful of all fittings that the earth had to be removed. The model lighting installation at Ft. Crockett, the Government post at Galveston, is equipped with earthed secondaries which have given rise to much lightning and fuse trouble, making it impossible also to replace fuses without making the lines dead. The climatic conditions at Galveston also make it necessary to use porcelain instead of wooden strain insulators, besides other modifications of standard construction practice.

Free Lamp Renewals in Chicago.—While discussing "Maintenance of Service" in a Paper read at a recent meeting of the Commonwealth Edison Branch of the National Electric Light Association, Mr. W. L. Abbott, chief operating engineer of the Commonwealth Edison Co., Chicago, gave some interesting information about the free lamp renewal service provided by his Company. The practice of exchanging good carbon filament incandescent lamps for burned-out or defective lamps was begun in 1895. At first customers had to call at the principal office to renew their lamps, but later, outlying depôts were established, and now the lamps are delivered at the customer's door on request. With the growth of the Company the cost of this free renewal service has assumed large proportions, and it now amounts to 32 per cent. of the total distributing cost, the free lamp renewals costing the Company about £100,000 a year. A bureau of the operating department is in charge of this work, and 12 telephone lines are needed to handle the incoming calls. Seven horse-drawn waggons and five electric waggons are used in delivering lamps to customers. Both classes of vehicles for this service present an attractive appearance. Tungsten lamps, which are not renewed free, are delivered by boys travelling on the tramcars, each boy carrying about 50 lamps. Carbon lamps are carried in trays, and both in the delivery waggons and in the stock room the position of the lamps in these trays indicates the character of the lamps. New lamps are placed in the trays with bases up, the old lamps being placed with tips up. By this simple method there is no trouble in distinguishing the good lamps from the bad ones. Lamps returned by customers are carefully tested. In the year 1910 it was found that about half the lamps returned were burned out. From 15 to 30 per cent. of the remainder were broken, and from 15 to 30 per cent. were found to be good after testing and were returned to service, many of them being used by the Company itself in sub-stations and elsewhere. It has been found that by handling the returned lamps carefully the percentage of serviceable lamps has been increased to a noticeable extent.

Coronation Honours.—The Coronation Honours list, which was published on Tuesday morning last, is freer from political bias than is usually the case. Nevertheless, we consider that engineering and physical science should receive greater recognition than it has on the last few occasions, for in cases where honours are given it is often too evidently for reasons quite apart from the scientific attainments of the recipients. It is perhaps not unworthy of note that no peerage has been con-

Digitized by Google

ferred purely for scientific attainments since 1897, when Lord Lister was so honoured. Surely it would not be difficult to find some scientist worthy of this honour The following names which appear in the list will be familiar to our readers :—

BARONS: *The Rt. Hon. Sir Chas. Benjamin Bright M'Laren, Bart.*, is actively interested in steel, shipbuilding and colliery undertakings. He is chairman of the Metropolitan Railway Co., and a director of the Tredegar Iron & Coal Co. and of John Brown & Co.

Sir Wm. Thomas Lewis, Bart., K.C.V.O., is a large employer of labour in South Wales in connection with the mining industries. He is a vice-president of the Iron and Steel Institute, and a member of the Council of the Institution of Civil Engineers. He has served on many Royal Commissions dealing with mining, shipping and trade disputes. He is a director of the South Wales Power Distribution Co. and of the Treforest Electric Consumers' Co.

BARONETS: *Herbert Samuel Leon, Esq.*, is a director of several electrical companies, including the Anglo-American Telegraph Co., the Smithfield Markets Electric Supply Co. and the Yorkshire (West Riding) Electric Tramways, being chairman of the two last-named.

C. T. Mander, Esq., is chairman of the Rees Roturbo Mfg. Co. and is intimately connected with other engineering work in and about Wolverhampton.

Sir Boverton Redwood, D.Sc., is an engineer and chemist who is well known for his researches on petroleum and its products. He is adviser on this subject to many Government departments. He is a past-president of the Society of Chemical Industry and a vice-president of the Royal Society of Arts.

Col. Arthur Griffith-Boscawen, M.P., is chairman of the Manx Electric Railway Co.

A. W. W. Dale, Esq., is principal of the University of Liverpool, and was formerly chairman of the Northern Universities Joint Matriculation Board.

John Purser Griffith, Esq., is engineer of the Dublin Port and Docks Board, and has rendered valuable services to the Royal Commission on Canals.

G. Croydon Marks, Esq., M.P., is senior partner in the well-known firm of Marks & Clerk, consulting engineers and patent agents. He is a director of the Bude Electric Supply Co. He has published a number of books dealing both with engineering and patent work.

K.C.B. : *Sir Robert Hunter, C.B.*, is solicitor to the General Post Office.

Alex. F. King, Esq., C.B., is second secretary at the General Post Office. Mr. King has charge of much of the telegraph work at St. Martin's-le-Grand.

Hon. Chas. A. Parsons, C.B., F.R.S., is, of course, well known to all readers of THE ELECTRICIAN as the inventor of the turbine that bears his name. He is managing director of the Parsons Marine Steam Turbine Co. and director of the Cambridge and Scarborough Electricity Supply Co.s. and the Parsons Foreign Patents Co. He was elected a Fellow of the Royal Society in 1898 and an honorary member of the Institution of Electrical Engineers in 1909.

Benjamin Arthur Whitelegge, Esq., C.B., M.D., has been Chief Inspector of Factories since 1896, and in this position is well known to readers of THE ELECTRICIAN.

James Alfred Ewing, C.B., F.R.S., has been Director of Naval Education since 1903, and before that was for some years Professor of Mechanism and Applied Mechanics at Cambridge. Prior to this he held similar positions at University College, Dundee, and at the Imperial University, Tokio. He has published works on magnetism, including "Magnetic Induction in Iron and other Metals" in THE ELECTRICIAN Series, and on steam engines. He delivered the "James Forrest" lecture in 1899 on "Magnetism" and the Kelvin lecture in 1910 on "The Work of Lord Kelvin in Telegraphy and Navigation." He was elected a Fellow of the Royal Society in 1887 and was awarded a Royal Medal in 1895.

Hay Frederick Donaldson, Esq., C.B., has been chief superintendent of the Royal Ordnance Factories at Woolwich since 1903. He is a member of the Councils of the Institution of Civil Engineers, Mechanical Engineers and the Iron and Steel Institute. He is also on the Board of the National Physical Laboratory, and is intimately connected with the work of the Engineering Standards Committee.

C.B. : *H. S. Carey, Esq.*, is assistant secretary at the General Post Office.

Edw. Rigg, Esq., I.S.O., is superintendent of operatives, at the Royal Mint.

G. Waller Wilcocks, Esq., K.C.M.G., is chief engineering inspector to the Local Government Board.

Arthur William Reinhold, Esq., F.R.S., is late professor of physics at the Royal Naval College, Greenwich. He has published Papers in the "Philosophical Transactions" dealing with the properties of thin films.

Col. H. C. L. Holden, F.R.S., is superintendent of the Royal Gun and Carriage Factories, Woolwich Arsenal. After serving in the Royal Artillery for some years, Col. Holden has since been employed on technical work connected with electricity and gunnery. He is the inventor of many instruments and apparatus both in these fields and in connection with motor cars.

K.C.M.G. : *John Rose Bradford, Esq., F.R.S.*, is a secretary of the Royal Society, and has also been prominently connected with the work of the University of London.

Current Topics.

Subjects of current interest dealt with in this issue include the following :—

Mr. A. H. Seabrook contributes an article on "Encouraging the Use of Electricity for Domestic Purposes other than Lighting."

Mr. W. A. Vignoles contributes an article on "Cheapening Services for Electricity Supply, with special reference to Three-wire Continuous-current Work."

Mr. C. E. C. Shawfield contributes an article on "Notes on Fuel Economy."

Mr. Justus Eck contributes an article on "Light and Shade in Indirect Lighting."

We describe the recent extensions at the Southwick power station of the Brighton Corporation. Particulars are also given of the installations of some large consumers connected to the electric supply mains.

An abstract is given of the annual report of Mr. G. Scott Ram, H.M. Electrical Inspector of Factories. The subject of accidents is dealt with in our Leading Article.

Particulars will be found on another page of the illuminated devices that have been erected in London in connection with the Coronation festivities.

The evidence at the public inquiry in connection with the recent Empire Theatre fire in Edinburgh is abstracted.

The Manchester electricity department has paid £15,000 to the city rate account out of the total net profits of £27,573 on the past year's working.

Parliamentary.—A Select Committee of the House of Commons has found partially proved the preamble of the Greater London Railway Bill, and certain sections of the original scheme were cut out.

In the House of Commons on Monday the Postmaster-General (Mr. Herbert Samuel), in introducing the Telephone Transfer Bill made a lengthy statement as to the intentions of the Government in regard to the future of the telephones.

Legal.—On Saturday Mr. Justice Swinfen-Eady delivered judgment in the action brought by the British Westinghouse Co. against the Electrical Co. for an injunction and for relief in regard to an alleged infringement of the Bremer flame arc lamp patent. After reviewing the evidence, his Lordship gave judgment for plaintiffs.

The Court of Appeal has concluded the hearing of the cross-appeal in the case of the National Telephone Co. *v.* the Postmaster-General but has reserved its judgment.

Companies' Meetings and Reports.—The statement presented by Chas. Rivers Wilson at the general meeting of the British Electric Traction Co. was made additionally interesting by his observations on the historical side of electric traction. Sir Charles announced his resignation as chairman.

At the meeting of the Victoria Falls & Transvaal Power Co. the Marquis of Winchester gave particulars of the development of the Company's undertaking in connection with the supply of electrical energy for mining on the Rand.

The report of Marconi's Wireless Telegraph Co. of New York for the past year gives some particulars of the position of wireless telegraphy in the United States.

At the meeting of the Aron Electricity Meter (Ltd.) on Tuesday the chairman, Mr. Hugo Hirst, gave particulars of the progress of the Company during the past year.

APPOINTMENTS VACANT AND FILLED.

A lecturer on the applications of electricity adapted for architects, &c., is advertised for.

A first-class mechanical and electrical engineer is required. He must have thorough experience in modern manufacture of c.c. and a.c. machinery. See advertisement.

A fully qualified draughtsman well up in electrical work (including switchboards and instruments) is required by Marconi's Wireless Telegraph Co., Watergate House, York-buildings, Adelphi, London, W.C. See an advertisement.

A draughtsman, with experience in building work for engineering and electrical purposes, is required for a consulting engineer's office. See an advertisement.

There is a vacancy for an electrical tester, with mains experience, in the Devonport Dockyard. Wages 45s. per week. Applications to the Electrical Engineer, H.M. Dockyard, Devonport. See advertisement.

A demonstrator in electrotechnology (£100 a year) and a visiting teacher of telegraphy and telephony (one evening per week, 10s

Digitized by Google

are required at L.C.C. Paddington Technical Institute. Application form (T. 17) can be obtained from the Education Officer, Victoria Embankment, W.C. Applications by 11 a.m. June 26.

Mr. Chas. S. Jeffrey, of Glasgow, has been appointed chief assistant electrical engineer to the Rangoon Electric Tramways & Supply Co.

Mr. J. Edwin Storr has been appointed to the vacancy on the staff of the Yorkshire Electric Power Co. occasioned by the resignation of Mr. H. M. Sillar.

Mr. H. J. Spencer (resident engineer to the Electric Supply Co. of Victoria at Ballarat) has been appointed resident engineer at the municipal electricity works, Redfern (N.S.W.).

INSTITUTIONS AND SOCIETIES.

Royal Society of Arts.—The Council of this Society, with the approval of the President, H.R.H. the Duke of Connaught, have awarded the Albert Medal of the Society for the current year to the Hon. Sir C. A. Parsons, K.C.B., F.R.S., for his experimental researches into the laws governing the efficient action of steam in engines of the turbine type, and for his invention of the re-action type of steam turbine and its practical applications to the generation of electricity, the ventilation of mines and other large spaces, blast-furnace work, ship propulsion and other important purposes. The beneficial results which have followed upon these inventions include a cheapening of the production of mechanical power, greater economy and speed for steamships, and the first successful solution of the problem of rotary engines which long had baffled many other inventors.

Tramway & Light Railways Association.—The "Journal" of this Association for June contains an illustrated report on the results of tram brake block tests undertaken by Mr. W. Thom, at the request of the Special Committee of the Association which is considering the question of "Brakes, &c.," a translation of one of the Papers read before the International Tramways Congress at Brussels by M. de Backer upon the results obtained in Belgium since the passing of the Light Railways Act in that country, and matters relating to the affairs of the Association generally. The "Journal" for July, which is to be published shortly, will be a special Congress number, containing the Papers which will be read at the Tramways Congress to be held at Edinburgh on July 13 and 14.

Faraday Society.—The following nominations for the Officers and Council (1911-1912), to be elected at the annual general meeting on June 11, have been made by the Council:—*President:* Dr. R. T. Glazebrook, C.B., F.R.S. *Vice-Presidents:* Messrs. G. T. Beilby, F.R.S., S. Z. de Ferranti, F. W. Harbord, Alex. Siemens, E. Solvay, Prof. J. Hopkinson, F.R.S., Prof. J. Walker, F.R.S. *Treasurer:* Mr. F. Mollwo Perkin. *Council:* Mr. E. J. Bevan, Dr. H. Borns, Mr. W. R. Bousfield, Mr. W. R. Cooper, Dr. J. A. Harker, F.R.S., Prof. A. K. Huntington, Dr. T. M. Lowry, Mr. R. L. Mond, Dr. G. Senter, and Mr. M. Solomon.

EDUCATIONAL NOTICE.

Heriot-Watt College, Edinburgh.—This college gives theoretical and practical training for mechanical, electrical and mining engineers, chemical chemists, &c. The training for engineers consists of three years in the college and three years apprenticeship, on the sandwich system, in a local engineering works. Further information may be obtained from the Principal of the College, Mr. A. P. Laurie, M.A., LL.D., or from the Heriot Trust Offices, 20, York-place, Edinburgh.

ARRANGEMENTS FOR THE WEEK.

TUESDAY, June 27th.

JUNIOR INSTITUTION OF ENGINEERS.

7 p.m. Special General Meeting of Contributors to the Benevolent Fund at 39, Victoria-street, S.W.

WEDNESDAY, June 28th.

INSTITUTION OF CIVIL ENGINEERS—CONFERENCE ON EDUCATION AND TRAINING OF ENGINEERS.

10 a.m. Meeting at Great George-street. Address by Mr. Alex. Siemens. Discussions on "The Extent to which Mathematical and Scientific Subjects should Share with Other Subjects of Literate Education the Attention of Schoolboys who intend to enter later the Engineering Profession," introduced by Dr. J. Gray and Prof. S. P. Thompson, F.R.S.; "The Question of specialised Entrance Examinations for University or College Courses of Study in Engineering Science with a View to the Curricula to be followed, and also of the Inclusion in the Latter of Courses in Modern Languages," introduced by Prof. A. K. Schwartz; "The Requirements of Practical Training and of Scientific Study and the Apportionment of Time to Them," introduced by Mr. A. F. Yarrow and members of his staff and Mr. W. H. Allen; and "Practical Training in Workshops or on Works of Construction, with Special Reference to Training in the Engineer's Office," by Mr. W. B. Worthington and Mr. H. F. Donaldson.

THURSDAY, June 29th.

INSTITUTION OF CIVIL ENGINEERS—CONFERENCE ON EDUCATION AND TRAINING OF ENGINEERS.

10 a.m. Meeting at Great George-street. Discussions on "The Value of a University Degree in Engineering Science in Relation to Professional Competence," introduced by Prof. S. M. Dixon and Prof. C. F. Jenkin; "The Position and Uses of Engineering Laboratories in Relation to Education at College," introduced by Prof. W. E. Dalby, Prof. John Goodman and Prof. B. Hopkinson, F.R.S.; "The Relation of Engineering Employers and Colleges from the Point of View of the Practical Training of College Students," introduced by Prof. J. E. Petavel, F.R.S., and Mr. J. W. Horne; "The Relation of Practical Training to College Study; Whether, or to What Extent, Before, Sandwiched, or after its Conclusion," introduced by Prof. A. Barr and Prof. H. Louis; "Workshop Training as a Preliminary to Practical Training in Other Branches of Engineering," introduced by Mr. J. A. Brodie, Mr. J. M. Moncrieff and Prof. J. J. Welch.

FRIDAY, June 30th.

PHYSICAL SOCIETY.

5 p.m. Meeting at the Imperial College of Science. *Agenda:* "On the Effect of a Narrow Sawcut in the Edge of a Conducting Strip on the Stream Lines in the Strip and on the Resistance of the Strip," by Prof. C. H. Lees, F.R.S.; "The Capacity Coefficients of Spherical Electrodes," by Dr. A. Russell; "Exhibition of the Benkö Primary Battery," by Mr. W. R. Cooper.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

TUESDAY, June 27th.

10 a.m. Meeting at the Royal Pavilion, Brighton. Welcome by the Mayor of Brighton (Councillor Thomas-Stanford). Presidential Address by Mr. John Christie (engineer and manager, Brighton Electricity Department). Papers on "Electricity Supply viewed from the Municipal Committee's Standpoint," by Councillor H. Leese (Stoke-on-Trent), and on "Modern Wiring Practice," by Mr. J. W. Beauchamp (chief electrical engineer, Tunbridge Wells).

2:45 p.m. Visit to the Southwick power house of the Electricity Department and to the works of the Brighton and Hove General Gas Co.

8 p.m. Reception and Conversazione at the Royal Pavilion by the Mayor and Mayoress of Brighton.

WEDNESDAY, June 28th.

8:30 a.m. Special Train (Brighton Central Station) for Portsmouth.

10:15 a.m. Meeting in the Lecture Hall, Municipal College, Portsmouth. Welcome by the Mayor of Portsmouth (Ald. T. Scott Foster). Papers on "Internal Combustion Engines working on the Diesel Principle," by Mr. H. L. Howard (chief electrical engineer, Barking), and on "Internal Combustion Engines for Power Stations" by Mr. R. M. Carr (chief electrical engineer, Leek).

2 p.m. Visit to H.M. Dockyard and the Power Houses of the Corporation Lighting and Tramways Committees.

5:30 p.m. Cruise in the Solent.

8:45 p.m. Special Train leaves Portsmouth Harbour Station for Brighton.

THURSDAY, June 29th.

10 a.m. Meeting in the Banqueting Room, Royal Pavilion, Brighton. Discussions on "Purchase of Fuel," opened by Mr. C. E. C. Shawfield (chief electrical engineer, Wolverhampton), and on "Street and Shop Front Lighting," opened by Mr. A. H. Seabrook (chief electrical engineer, Marylebone).

2:45 p.m. Visit to the Church-street Sub-station and the Locomotive Works of the L.B. & S.C. Railway.

7 p.m. Annual Dinner at the Dome.

FRIDAY, June 30th.

10 a.m. Annual General Meeting at the Royal Pavilion.

2:30 p.m. Motor trip to Arundel.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued for the current week:—

Monday, June 26th, "A" Company.—Technical Drill, 7 p.m. to 9 p.m.
Tuesday, June 27th, "B" Company.—Technical Drill, 7 p.m. to 9 p.m.
Wednesday, June 28th.—Gymnastic Classes, 7 to 10 p.m.
Thursday, June 29th, "C" Company.—Technical Drill, 7 to 10 p.m.
Friday, June 30th, "D" Company.—Technical Drill, 7 to 10 p.m.
Saturday, July 1st.—Felixstowe Detachment, parade at Headquarters at 1 p.m.:—Dress: Service dress, drill order. Arms will be drawn at Headquarters before the parade.

Digitized by Google

ANNUAL REPORT OF THE ELECTRICAL INSPECTOR OF FACTORIES.

In our last issue we referred to the chief points of electrical interest in the Annual Report for 1910 of Dr. B. A. Whitelegge, C.B., H.M. Chief Inspector of Factories. Accompanying this Report are several sectional Reports, including that of Mr. G. Scott Ram, H.M. Electrical Inspector of Factories. As this Report is of considerable importance the following abstract will prove of interest :—

The Regulations which became operative as regards the use of electrical energy in factories and workshops on July 1, 1909, came fully into force in generating stations on January 1, 1910. The memorandum explaining the effect of the Regulations and the exemptions allowed in the several classes of works and installations to which they apply was issued in February, and has proved of very great service in replying to occupiers and others asking for information, and has fully justified the labour spent in its preparation. Some questions have arisen as to whether certain forms or conditions of the transformation or conversion of electrical energy constitute "electrical stations." Thus, electrical energy taken from public supply mains is passed through motor generators, converters or rectifiers for use in cinematograph lanterns, or for the charging of secondary batteries. So long as the use of the transformed or converted energy is solely for the purposes of throwing pictures on a screen or for charging batteries, the transformation does not fall within the definition. If, however, the transformer or converter is on premises already under the Acts the Regulations will apply.

With regard to the observance of the Regulations generally, while many occupiers have taken trouble to ascertain if their installations are in conformity with the requirements, and have taken steps to put them in order where necessary, a large number have done nothing pending instructions from the Inspectors. Although it is the duty of the occupier to provide compliance without waiting for instructions, there are several circumstances which operate to cause delay. First and foremost is the fact that a vast number of occupiers, although making use of electrical energy in their works, understand little or nothing about it, and are quite incapable of determining whether the Regulations are complied with or not. In large works where an electrical engineer is employed the occupier may take his advice and do what appears necessary, but more often he hesitates to do anything until an Inspector points out the necessity. Moreover, the requirements were purposely drawn so as to give the utmost latitude in the design of apparatus and methods of protection, so as not to check or retard progress, provided that the object—safety to the user and other persons employed—is attained. Untechnical occupiers are naturally unable to decide whether there is safety or not, and even amongst electrical engineers many points of danger are apt to escape their notice until pointed out. Reports from some of the Inspectors show, however, that a good deal of work has been done in getting some of the more obvious defects remedied, such as bare conductors, fuses, switches, &c., protected, defective switches, &c., repaired.

In general, whilst more accidents causing burns occur with direct-current apparatus, the fatal shock accidents are nearly all with alternating current.

Several inspectors point out that in many districts the Corporations supplying electrical energy have their own rules as regards the consumer's installation and which in some cases are more strict than the Regulations, and that consequently the latter are well carried out, also that in some cases the electrical supply authorities have altered their own previous regulations to coincide with those under the Factory Acts. It is certainly to the advantage of the occupier when the supply undertakers look carefully after his installation. This supervision is not, however, universal; there are others, some being local authorities, who do not trouble about their consumers' installations in any way beyond making an insulation test before starting to give a supply. Further than this, some even hand over to the occupier the care of their service fuses. In some instances of fuse boxes left unsealed, they were probably deliberately left so that the occupiers could renew the fuses themselves. A stoppage due to blown fuses may, of course, prove expensive in the case of a large factory. Ordinarily service fuses are sealed up by the supply authorities, and are exempt from the Regulations. If, however, the occupier has access thereto, necessitating the exposure of live metal, the exemption does not apply, and the Regulations must be complied with. As the responsibility in such cases for the provision of suitable fuse gear is necessarily placed by the Regulations upon the occupier, the Department cannot call upon the supply authority to make the necessary provisions, but they can bring pressure to bear by proceeding against the occupier for a breach of the Regulations, and if necessary could prevent the use of electrical supply until the matter had been put in order by the supply authority. It is important, therefore, that supply authorities should recognise that service fuses on factory premises, if unsealed, and accessible to the occupier are subject to the Regulations.

Non-compliance with the Regulations is not by any means limited to old installations. I have come across some important plants, put up since the Regulations came into force and by well-known firms of electrical contractors, where the Regulations have evidently not been taken into consideration. In one case where the space at the back of a switchboard was 18 in. instead of the required 3 ft. passage the work had been put in under the supervision of a consulting engineer. Unfortunately for the occupier in such cases, it is he who is responsible under the Factory Acts. Some contractors and even a representative of a firm of consulting engineers admit not having seen a copy of the Regulations. The record of accidents for the year shows on investigation that the conditions leading up to the accidents in the majority of cases were such as neither complied with the definite requirements of the Regulations nor suggested any alternative means of safety.

As pointed out in my last year's report, non-compliance in certain particulars is often brought about by the use of unsuitable and dangerous apparatus supplied by electrical manufacturing firms. There are still many faulty designs of switches, fuses, connectors, hand lamps, &c., which continue to be re-produced. Several firms are, however, taking up the manufacture of articles specially designed to meet the requirements as to safety. Considerable attention has been given by manufacturers to the production of safe fuse-holders. One of the requirements is that fuses, unless protected by a switch cutting off all pressure, must be designed so that they may be handled with safety for the purpose of renewing a fuse, and this is a point which has been overlooked in many of the patterns commonly met with. I have noticed in my visits a tendency to the use of fuses or switch-fuses for very large currents under conditions where circuit-breakers would undoubtedly be safer and more suitable. This is probably due to the latter being somewhat more expensive. A type of fuse which has recently come into considerable favour has a porcelain cartridge fitting into contacts enclosed in a porcelain base. It is arranged so that it can be handled for renewal without danger of touching live metal, but it is not intended for use as a switch-fuse. It has an indicator for showing when a fuse has blown. One of the chief features is that the proper size of fuse for the circuit having been determined upon, the base is set to take that size of cartridge and no other. It is impossible for an unauthorised person to over-fuse the circuit by inserting a fuse of larger capacity. The cartridges contain the smallest possible amount of metal in the fuse, with the result that they break circuit without report or explosion under very severe conditions.

Attention has also been given to the construction and protection of automatic circuit-breakers. Many types of direct-current circuit-breakers are dangerous, particularly when used in confined spaces such as the driving cabins of cranes, through exposed live metal and from the flash or scattering of hot particles of metal when they come into operation. Enclosed circuit-breakers designed to overcome these defects have now been produced. The design of oil switches and circuit-breakers has also received consideration from several makers, with a view to preventing the possibility of explosion.

Unsatisfactory and dangerous work is often due to the cutting of price and acceptance of the lowest tender.

With regard to public supply stations, in many cases the question o compliance with the Regulations has been carefully gone into, but i others a waiting policy has been adopted. In several instances new mai switchboards have been put in, and in others steps are being taken t that end. In these cases the discarded switchboards have been anythin but satisfactory to the station engineers, who have been very glad of th assistance afforded them by the Regulations in obtaining the necessar grants for carrying out the alterations. A good deal of work has bee necessary in some cases to provide compliance with the regulation whic requires protection of conductors in the passage-ways of high-pressu switchboards. Safe means for operating high-tension isolating switch is also a matter which has had to be dealt with in several instances.

One of the most important of the Regulations (No. 28) provides again the employment of (technically) ignorant persons where there is dange Arising out of fatal accidents, two prosecutions under sec. 136 we undertaken against electric power companies for breaches of this an other regulations. In one case the company pleaded guilty and was fine £20. In the other, which was defended, a fine of £10 was imposed. The have been many instances of accidents, fatal and otherwise, under su circumstances, and this regulation was specially devised in consequen As I have pointed out in former reports, an ignorant (electrical person, whether an unskilled labourer or a skilled artizan, such as bricklayer, plumber or carpenter, cannot realise the danger to which is exposed. As has been repeatedly proved, it is of no use to tell him to careful not to touch certain conductors or apparatus where he is worki These conductors appear to him to be no more dangerous than a gas p or a water tap. If it is necessary to employ such persons near l conductors, the live conductors must first be so screened off that ther no danger. If work has actually to be done under conditions wh there is danger, then it is only fair that a competent electrical engin or other person with adequate technical knowledge should undertake it

The increasing use of electrical energy for motive power in factorie again indicated by the figures taken from the annual returns of hor power of motors connected to the mains of electricity supply undertaki published by THE ELECTRICIAN. Although the figures are not compl a number of undertakings giving no return and the large power compa not being included, an addition of 70,000 H.P. during the year is accoun for, bringing the known total of motors connected to public supply m up to over 630,000. In spite of the low price at which electrical ene can be purchased in many districts, occupiers of large works continu put down new electrical generating plant of their own.

Table I. summarises the accidents at electrical generating stations sub-stations.

The mechanical accidents are somewhat fewer than in the prev year (319 and 38), the reduction being chiefly under the heading "falls." The electrical accidents are also fewer, the number of fatalit four, being however the same. The actual figure, 45, for the pu supply stations, is remarkably small, and compares with 58 and 76 in

Unskilled persons	—	—
Adjusting brushes and cleaning commutators	2	1
Miscellaneous	7 (1)	3
Total	45 (4)	13

two previous years. When it is considered that the output of the electricity supply undertakings increases enormously every year, and that in the earlier tables returns from tramway undertakings (other than those having combined stations for general supply and traction) were not included, it is evident that the relative proportion of accidents to the total output of electrical energy from the stations has fallen greatly, indicating a higher standard of safety as regards the plant and apparatus, and greater care on the part of those responsible for its operation. The Regulations may be assumed to have had a beneficial influence upon the result.

The nature of the accidents is much the same as I have described in previous reports. Several accidents from short-circuit, resulting in severe burns, were obviously due to carelessness. Thus, there were again the cases of men taking measurements of switchboards with steel rules, whilst two men were injured through "levelling" a live switch with a metal spirit-level, and another through the use of a stick of solder. Two of the four fatal electrical cases were due to men without technical knowledge working near electrical apparatus; a third case occurred during the cleaning of an extra-high pressure board supposed to be "dead." Whilst under the miscellaneous accidents, the fatal case occurred to a cleaner at an extra-high tension switchboard in a sub-station, who for some unexplained reason, probably mere curiosity, obtained the key and opened the door of a live panel.

Table II.—*Electrical Accidents in Factories other than Electrical Stations in* 1910.

The figures in brackets relate to fatal accidents and are included in the principal figures.

Arcing of { switches	48
Arcing of { fuses	13
Shock or burns from fuses when replacing fuse-wires	28 (1)
Flexible apparatus, connectors and flexible wires	54 (1)
Unprotected conductors, switches, terminals, fuses, &c.	21 (1)
Working on or near live conductors { Skilled persons	34
Working on or near live conductors { Unskilled persons	17
Miscellaneous accidents in electrical manufacturing works—mostly in testing operations	30 (1)
Adjusting brushes and cleaning commutators	7
Miscellaneous	24 (1)
Total	276 (5)

The total number of the accidents recorded in Table II. is slightly greater than last year. The increase of 18 accidents, or 7 per cent., is however, much less than would be the case if, as might be expected, the rate of increase in accidents should coincide with the rate of increase in the use of electrical energy. The number of fatalities is five as against eight for last year.

The accidents from the arcing of switches, including motor-starting switches, are mostly due to defective design or to the switches not being maintained in good order. A number are due to motor-starting switches having a no-volt release not being maintained in proper order, and failing to return to the starting position. On the next occasion when the motor switch is put on there is consequently a flash, and the man gets his hand burned. The accidents from the arcing of fuses are in nearly all cases due to absence of protection of the fuses, and are consequently due to a breach of the Regulations. Similarly with automatic cut-outs, which are often placed at the height of a man's face and sometimes in a confined space.

The accidents in the use of portable apparatus are rather numerous. Twenty occurred in handling the flexible wires, some being due to wires, originally well insulated and protected, being kept in use after the covering had been damaged or worn out, but others to the use of a "drawing-room" class of flexible in place of a well-protected "workshop" quality.

Twenty-four accidents were due to the use of unsuitable plug connectors, fifteen of which were of the two-pin wall type and nine of the "adapter" type where the connection is made to a lamp-holder. Both last year and the year before I described how a connector plug should be made so as to obviate the dangers. Such plugs are now obtainable from several manufacturers. In the fatal case a hand lamp with flexible wires was being connected by means of an "adapter" to a lamp-holder. The lamp-holder, which was a fixture, was placed above a metal platform in a boiler-house, so that the man standing on the platform was in connection with earth. In holding the adapter to put it into the lamp socket, the flexible wires would pass through the man's hand. The insulation on the wires was damaged at this point, so that he touched the bare wire. No switch was provided for cutting off the pressure to the lamp socket, so that as soon as the adapter made contact the flexible wires became live, and the man received a shock to earth. The current was alternating, and as frequently happens in such cases, the man was unable to move or let go or even to make the simple movement necessary to take the adapter out of the lamp-holder. Although assistance was at hand in a very short time, he was killed. The pressure on the lamp circuit was 115 volts, but as the circuit was taken from an auto-transformer from a 230-volt circuit, the pressure of the shock was probably 230 volts.

Fifty accidents were due to persons working on live switchboards and other conductors. The skilled persons are described as "electricians" or "wiremen," and probably would be cognisant of the risks they were running. As I have frequently pointed out, there is seldom any real need for such work on factory premises, as the work can be done when the conductors are dead, even if it is necessary to wait until after factory hours. The unskilled persons, variously described as "labourer," "handy-man," "fitter," "engine driver," &c., should not have been allowed to undertake such work.

Testing operations in electrical manufacturing works are carried on very largely by pupils and apprentices, and it is chiefly amongst them that the accidents occur. The average age of 26 of the 30 persons meeting with accidents was only 22 years. Carelessness due to want of experience and insufficient supervision are no doubt contributory causes. On the other hand, the means provided for carrying on the tests are often faulty. Thus, old pieces of cable with the insulation worn out are used for making connections, and switches which are out of order are used for making and breaking circuit. The fatal accident, which happened to a competent man of long experience, occurred in connection with a pressure test, and appears to have been due to a mistake in signalling, the man touching the piece of apparatus under test thinking that the pressure had been cut off by the attendant at the switch some distance away.

In Table III. are set out the fatal cases mentioned above.

Table III.—*Electrical Fatalities reported under the Factory Acts in* 1910.

No.	Month.	District.	Voltage of System.	Probable voltage of shock.	System. A = Alternating, 1 = Single-phase 2 = Two-phase. 3 = Three-phase, D = Direct.

ENCOURAGING THE USE OF ELECTRICITY FOR DOMESTIC PURPOSES OTHER THAN LIGHTING.

BY A. HUGH SEABROOK.

Summary.—The author considers briefly the bearing of the following upon this problem: The tariff, the "business-getting" department, showrooms, hiring, accounts, hire purchase, cookers and the business instinct. Examples are given of the methods followed by the author in the St. Marylebone undertaking.

The two essentials to effect this result are :—

(*a*) A suitable tariff.

(*b*) An efficient business-getting staff.

Each is as important as the other, and the one will not effect any substantial result without the other.

The result of this combination in St. Marylebone has been that during the year ending March 31, 1911, we increased our connections for "other uses" by no less than 800 kw. (largely in residences), as compared with an increase of 285 kw. during the previous year.

Tariff.

The only tariff which will encourage "other uses" is a differential tariff in which the primary charge is *not* in the form of so many units at a high price per unit, but based on the connected lighting load (the most preferable basis), rateable value, number of rooms or area of rooms. Obviously, no differential system employing current limiters is suitable, because "other uses" apparatus in that case cannot be connected to the lighting mains, *and only a tariff which permits this apparatus to be connected to the lighting mains is effective in encouraging "other uses" of electricity.*

In these tariffs referred to the secondary rate is a low price per unit, generally 1d., and the tariffs are so framed that the standing charges of the domestic electric service are based on the lighting installation, and it is assumed that electric light is used throughout the house. All apparatus other than lighting can then be connected to the lighting system where the latter will carry it, the only charge made being the low secondary charge per unit; the primary charge is not increased on account of "other apparatus." I consider it to be perfectly justifiable to insist upon the complete installation of electric light in a house before a consumer can have current for "other uses" at the secondary charge only. I am convinced that the proper way to make reductions in price to consumers is to offer something in return for a *quid pro quo*. I do not believe in making concessions and getting nothing in return.

The method of application is as follows: Suppose a consumer wants to put in "other apparatus," and we find he only partially uses electric light, and uses (as is generally the case) gas in the long-hour part of his house—*i.e.*, the basement—we say our charge for "other uses" is 2d. and 1d. on the maximum demand system; but "if you will *wire your house throughout* and enter into a contract on our 'telephone' system, you can have all units at 1d."

Our before-mentioned increase of 800 kw. has been obtained in spite of this insistence upon a complete lighting installation, and some people may argue that that might be a serious difficulty in the way of encouraging "other uses." So it is, where there is not an *efficient business-getting department* in addition to the suitable tariff; in fact, I should imagine it is a well-nigh insuperable difficulty.

One point in connection with the suitable tariff before I leave it. There are many people who believe that a differential tariff, with its primary charge based on the connected lighting load, is a good one; but they say that it—

(*a*) Prevents the liberal installation of lamps—*i.e.*, lamps will only be put in where absolutely necessary; and

(*b*) They do not know what to assess the primary charge on.

Taking (*a*) first. It is usual in a tariff of this kind to insist upon the complete electric lighting of the house, but to count as connected lamps only those in general use. All lamps, such as those used in cupboards, cellars, lavatories, bathrooms, larders and also all purely decorative lamps, &c., which are only turned on for occasional use, are termed "convenience" or "inactive" lamps. It is well known, by all who have taken the trouble to ascertain, that the liberal installation of "occasional" lamps, by increasing the diversity factor of the residence, improves its load factor, so that any tariff which discourages these lamps should be avoided.

Then, as to (*b*). When "convenience" lamps are counted out, it is generally found that the average residence uses 70 per cent. of its watts installed for lighting at any one time. This may sound a high percentage for large houses compared with the percentage usually shown by them on the maximum demand system, but it must be borne in mind that the larger the house the larger is the number of convenience and decorative lamps in use, and it will be found that 70 per cent. is about right. I notice Mr. Ayton, of Ipswich, takes 60 per cent., and Mr. Cottam, of Hampstead, about the same figure.

The following is a letter sent to all consumers adopting the "telephone" system, pointing out how cheaply "other apparatus" can be used :—

BOROUGH OF ST. MARYLEBONE ELECTRIC SUPPLY.

Dear ————,

Re "Telephone" System of Charging.

The "telephone" system of charging having been well taken up by consumers, it may not be out of place for me to remind you that, having adopted the system, the following advantages are yours :—

1. The most lavish use of electric light only increases the number of *1d. units.*

2. Once the annual charge is paid, electric light only costs *1d. per unit.*

3. It is not extravagant to use electric light freely on dark and dull days and in dark places at *1d. per unit.*

4. Waste of light in any direction, for instance, basements and servants' quarters, is only a matter of *1d. per unit.*

5. Auxiliary uses of electricity—ironing, grilling, fans, &c.—can be effected by connecting the apparatus to any convenient lamp-holder or plug in any room at a charge of *1d. per unit*, resulting in a saving in special wiring and meter rents.

6. Cooking and heating only cost *1d. per unit*, at which price electricity is *as cheap as* gas for these purposes.

We have already received over £20,000 in annual payments, which illustrates the popularity of the scheme.

Yours faithfully,

General Manager.

Business-getting Department.

Whether it is called Sales, Publicity, Commercial, Consumers' or any other name, the important thing is for every electric supply undertaking to have one.

One of its most important functions is not only to *get* business, but to *keep* it. In fact, it is getting increasingly difficult to keep existing business, and in my opinion it is preferable to effect this by employing a competent staff to keep in touch with consumers than to make wholesale reductions in price in order to keep consumers. At any rate, it is much less expensive to the undertaking.

A business-getting and keeping staff is of the utmost importance in encouraging the "other uses" of electricity. As an example, a woman buys an electric iron or a kettle, and perhaps after a time the "flex" breaks down, or the kettle is allowed to boil dry. *If there is no staff keeping in touch with the consumer that kettle and iron get put on the shelf or the scrap heap, and the supply undertaking never knows that they are out of commission.*

When such a staff as I have mentioned is in existence consumers very soon begin to know about them, and ring up immediately the least little thing goes wrong; in fact, they are in hasty moments, considered rather a nuisance, but that is only the temptation of the "old Adam" of the old times, when a consumer who dared to complain was promptly consigned to perdition.

We send frequent reminders to consumers as to keeping their apparatus in proper working order, and the following is one of them :—

BOROUGH OF ST. MARYLEBONE ELECTRIC SUPPLY.

Consumers are earnestly requested to let us know if any of their electrical apparatus, such as fans, radiators, irons, ovens, kettles, &c., are not in working order.

Frequently the faults are such that we can put the apparatus in order free of charge, and where this is impossible we will quote a low price for the repair.

Digitized by Google

We wish to know of *all trouble of every kind*, so that we may have, at least, an opportunity of putting it right.

All that is necessary is to send a postcard instructing our representative to call at a stated time, either day or evening.

We fully realise—as a public-service undertaking—our obligations to our consumers, and it is our constant care to fulfil these obligations.

Any consumer experiencing any such failure on our part to carry this out would confer a favour by reporting it in writing immediately to the general manager.

There is a further advantage in looking after consumers' apparatus, because during every call our representative mentions some of the new domestic electrical apparatus which is constantly being put on the market, and probably leaves an illustrated pamphlet. He confirms the call by letter when he returns to the office; thus the consumer has a permanent record of the call and the apparatus talked about. To show that consumers do take notice of such letters and calls, we frequently receive orders for the apparatus months after our man has called; but in any case we do not forget it, because all calls, matters discussed, apparatus sold, &c., are entered on the consumer's card in the office.

The staff of this business-getting department works in very close touch with the accounts and mains departments. A much larger percentage of our "other apparatus" sales results from account complaints than would be imagined. All account complaints are dealt with by the business-getting staff, and the consumer is called on immediately upon receipt of the complaint. In many cases, by adopting a different tariff or using metal lamps, the consumer is shown how he can cut down his electric-light cost, and when satisfied as regards his light and not before, he is prepared to listen to the "other uses" to which we can put his electric service.

Trial Offers.

An offer to loan apparatus for short periods is a most effective way of introducing domestic electrical apparatus, and the sales resulting therefrom are most gratifying.

Two examples follow of the circular sent, generally with the quarterly accounts.

BOROUGH OF ST. MARYLEBONE ELECTRIC SUPPLY.

ELECTRIC FANS.

We shall be glad to send a competent representative to call upon you and supply any information you may require as to Electric Fans, if you will kindly fill in, tear off and send us the lower part of this form.

.....

To the GENERAL MANAGER,
Borough of St. Marylebone Electric Supply.
Please send a representative on.....next to give full information as to Electric Fans.

Address .....

Date.....191 .

BOROUGH OF ST. MARYLEBONE ELECTRIC SUPPLY.

SPECIAL TRIAL OFFER OF ELECTRIC IRONS.

We are prepared to supply you with one electric iron for a trial period of one month. If you would care to avail yourself of this offer, please sign (at the perforation) and sign the attached note.

A man in uniform will deliver the iron, upon receipt of the trial order, and will ask for a receipt to the effect that the iron has been delivered. He will call again in one month's time, and either receive an order from you for the iron or take it away.

No liability attaches to you in respect of the iron in the event of its not being purchased, except as regards current consumption. The price, if purchased, is 12s. 6d., and *it only uses about one-fifth of a unit per hour.*

Please have nothing to do with any person in connection with this transaction who does not wear the official uniform and does not produce his card.

.....

To the GENERAL MANAGER,
Borough of St. Marylebone Electric Supply.
Please send me one electric iron to use during a trial period of one month.
I do not undertake to purchase it even if it acts satisfactorily.
I accept the iron on the understanding that no liability rests with me in connection with it during the trial, except as regards consumption of current.

Signed.....

Address .....

Date.....191 .

Showrooms.

The supply undertaking must have showrooms where consumers can see all kinds of apparatus working, and where they can call for particulars as to rates of charge, &c.

An ideal showroom, in my opinion, should be situated on a ground floor, and it should not look like a sale room, but it *must* look like a sale room if space is limited. Near the entrance should be a commissionaire to wait on callers in fine and wet weather, just as they would be waited on at a large store. Inside should be a waiting room or lounge, with comfortable chesterfields and armchairs, and a small table near with the department's literature on it. Leading from the lounge should be a wide passage, and standing on each side of it various appliances, such as vacuum cleaners, radiators, cookers and so on. At the end of the passage are the cashiers' desks. Leading off from the lounge and passage (there should be no permanent partitions on this floor at all, merely columns for supporting the floors above) are the model kitchen, bathroom, bedroom, nursery, dining room and so on. They can be quite tastefully arranged by avoiding permanent partitions, and in each room is placed and shown working the various electrical apparatus which is suitable to be used in it. To my mind this is much to be preferred to the present usual arrangement of odd kettles, irons, fans, radiators, &c., standing about promiscuously, and which, I am sorry to say, owing to lack of space, is the arrangement in our own showroom.

A consumer sees a kettle among a lot of other things, which latter distract his mind from the kettle; but if he sees that kettle doing its proper work in its proper room he will be much more impressed with it.

The showroom windows, on the same principle, should not look like shop windows, and all through the showrooms the idea should be to impress the consumer that a public service is being sold, and not apparatus, the selling of the apparatus being only incidental to the selling of the service.

This may strike the average supply manager as a somewhat elaborate arrangement; but let him look back five years and note the advance made in showrooms since that time, and let him bear in mind that in the future the business side of electric supply is going to take its proper place in relation to the general undertaking, as it does already in other branches of commerce.

Hire.

In order to do a considerable business in electric domestic appliances it is necessary to *offer* hire terms. I say "offer" because it does not necessarily mean actually hiring in all cases; in fact, it is surprising the small amount of apparatus that we hire out in St. Marylebone, though I am convinced the possibility of being able to hire is useful in introducing the apparatus to the consumer. If we approach him on the basis of a direct sale he will probably turn it down, but if he is approached on a hire basis he pays more attention to the proposition, and though he sometimes hires, he generally buys. I think the explanation is that, in common with the general public, he has no idea that electrical apparatus is so far advanced that anyone has the courage to offer it on hire terms.

Hire of apparatus is no good as a business deal unless a very high rental can be obtained. On small apparatus it should be 50 per cent. per annum on the capital value, decreasing with larger apparatus, such as vacuum cleaners, and lowest of all in the case of cookers, which is the class of domestic apparatus it is most desirable to introduce. The high hire charges on small apparatus keep it down to reasonable limits, and make it a profitable business. As I said before, the main idea is to be able to talk to the consumer in hire terms if necessary.

Adjoining is a sample of our hire-agreement form.

Representative..... District..... No.....

METROPOLITAN BOROUGH OF ST. MARYLEBONE

Quotation dated .....

Sixpenny Stamp.

CONDITIONS.

1. The Council will bear the expense of repairs and renewals to the fittings arising from defective material, workmanship or design and fair wear and tear therein subject to the conditions of article 2 hereof but except as provided by this article the Council will not be liable for any loss or damage whatsoever caused by or consequent upon any breakdown or failure of the fittings.
2. The hirer shall be responsible for and shall bear the cost of making good all loss injury or damage of or to the fittings, however caused, except to the extent provided for by article 1 hereof and shall from time to time keep the same in good condition and substantial repair (fair wear and tear only excepted), but all repairs of and other work executed in connection with the fittings for which the hirer shall be liable as hereinbefore provided, shall be effected at the hirer's expense by the Council's servants or (at the option of the Council) by a person approved by them. The hirer shall forthwith give notice to the Council of any breakdown, failure, loss, injury or damage of or to the fittings. The hirer shall, during the hiring, insure and keep insured for their full value, the fittings against loss or damage by fire and any sum received by the hirer under such insurance shall be a debt due from him and shall be paid by him to the Council, and the Council, on receipt thereof, shall repair or renew the fittings as they may think fit, and no rent shall be payable by the hirer in respect thereof during the time occupied by such repair or renewal.
3. The Council's servants shall be at liberty at all reasonable times to enter the said premises for the purpose of inspecting the fittings and or effecting any repairs or renewals.
4. The hirer shall not remove the fittings or any part thereof from the said premises or attempt to assign, let on hire, charge, or in anywise deal with the same without the consent in writing of the Council previously had and obtained.
5. The Council's name plate, mark or brand shall not on any account be removed from the fittings or in any way defaced or obliterated.
6. The hirer agrees to take from the Council during the continuance of this agreement the whole of the electrical energy required for the said fittings.
7. If any rent or other sum due under this agreement shall be unpaid for seven days after the same is due and whether the same has been demanded or not or if the hirer shall file a petition in bankruptcy or shall have a receiving order in bankruptcy made against him or shall make any composition or arrangement with his creditors or any of them, or commit any act of bankruptcy or shall resolve or be ordered to be wound up or if he shall not duly observe and perform the terms and conditions of this agreement or any of them, then and in such case and in addition to any other right or powers possessed by the Council, it shall be lawful for the Council or their agents and servants on their behalf, although the Council may not have taken advantage of some previous breach or default or event (of a like nature or not) forthwith to put an end to the hiring and to enter upon the said premises to take possession of and remove the fittings and forthwith to recover any sum then due, together with the reasonable expenses of such discontinuance and upon such discontinuance the hiring shall cease, but without prejudice to any right which shall have then accrued. In the event of such discontinuance the hirer shall also pay the Council a sum equal to the rent of the fittings until the expiration of the period at which this agreement could have been determined by the hirer giving notice in accordance with the provisions of the agreement.
8. Any notice or demand under this agreement shall be sufficiently served if sent to the hirer by prepaid registered post addressed to him at the said premises.
9. The several words and expressions to which meanings are assigned by the Electric Lighting Acts, 1882 and 1909, the St. Marylebone Electric Lighting Acts, 1901 to 1904, and the Board of Trade and the Home Office Regulations have the same respective meanings in this agreement.

Maintenance.

The maintaining of consumers' lighting installations is most desirable because it keeps our business-getting staff (who look after the maintenance) in the closest possible touch with consumers; thus we know, for instance, when a new baby arrives, and can put forward suitable electrical nursery apparatus in an inobtrusive way, and talk about the extreme safety and desirability of electric radiators, milk warmers, airing apparatus and so on.

All our maintenance men wear a distinctive uniform and put on over-shoes in consumers' houses; they are also trained business-keepers and getters.

The following is a sample of our maintenance agreement. The idea of keeping these agreements small is that our representatives can carry the books in their pockets, and get the form signed and the business closed on the spot.

Representative..... District..... No.....

METROPOLITAN BOROUGH OF ST. MARYLEBONE
ELECTRICITY DEPARTMENT.

Agreement for Maintenance.

The Mayor, Aldermen and Councillors (hereinafter called " the Council ") at the request of.....
(" the consumer ") hereby agree to maintain the electric lighting installation at the premises occupied by the consumer at.....
.....
from.....till.....in the manner and upon the conditions set forth on the back hereof, for the sum of £.....per annum.

And the consumer hereby agrees to observe and perform the said conditions and to pay the said yearly sum in four quarterly payments regularly and punctually.

Dated the.....day of.....191 .

Signed on behalf of the Council.....
Town Clerk or General Manager.

Signature of consumer.....

Witness .....

Quotation dated .....

Sixpenny Stamp.

CONDITIONS.

1. The Council are to maintain all lamps in an efficient lighting condition, replace lamps which fail, clean shades and globes, inspect and renew fuses, inspect the installation generally, and test the installation at least once a quarter; but material and labour for repairs, renewals or alterations to the installation other than as above stated, are not included.
2. If the tests and inspection show it to be necessary for repairs, renewals or alterations to be carried out, an estimate is to be given for the work required, except in cases of small matters dealt with by the maintenance attendant at the time of his visit, according to the consumer's instructions, for which a reasonable charge will be made.
3. The consumer is to notify the electricity department on the occasions of the premises being overhauled for decorating purposes, &c., so that steps may be taken to prevent damage to lamps, and the Council is to be entitled to charge for all lamps which fail through rough usage.
4. The Council may determine their obligation to maintain at any time by a calendar month's notice in writing, in which event the proportion of the yearly sum to date of determination shall be payable immediately.

Account Forms.

No opportunity is lost of saying something about "other uses." All account forms have the following note or something akin to it:—

> If you adopt the "Telephone" System for lighting you can have electricity for heating, cooking, &c., at 1d. per unit. Our representative will call on receipt of a postcard.

> ELECTRIC RADIATORS are unrivalled for HEALTHY AND CHEAP HEATING.

In addition, each envelope containing the first application, second application and receipt also contains a leaflet on some particular apparatus, or a slip as follows:

The celebrated international dinner of 14 courses, which everyone has been talking about, given recently at the House of the Institute of Hygiene, Devonshire-street, W., was cooked by electricity in an ordinary "Marylebone" electric cooker.

It was only to be expected that such an Institute would press into its service the most hygienic agent known to modern science—viz., electricity; but when it is remembered that electricity is not only hygienic but cheap as well, and that electrical cooking apparatus is so far advanced in manufacture and standardisation that it can be hired out to consumers, then it behoves all householders who have any regard for hygiene (and, fortunately, they are an ever-increasing number) to adopt electricity for cooking.

BOROUGH OF ST. MARYLEBONE ELECTRIC SUPPLY.
19 and 20, York-place, Baker-street.

I do not propose to touch any further on this matter of the value of advertising and publicity as a means of increasing the "other uses" of electricity, as managers of supply undertakings cannot do better than adopt the suggestions of the chairman of the Electric Supply Publicity Committee in his periodical circular, and then to supplement them by local advertising in their own areas.

Hire-Purchase.

Just a word as to hire-purchase of apparatus.

The best basis is to charge 25 per cent. of the total price of the work in advance and before the work is commenced, then the balance to be paid off in eight quarterly instalments.

Digitized by Google

The following is a sample of our hire-purchase form :—

Representative..... District..... No.....

METROPOLITAN BOROUGH OF ST. MARYLEBONE
ELECTRICITY DEPARTMENT.

AGREEMENT FOR HIRE-PURCHASE OF FITTINGS.

The Mayor, Aldermen and Councillors (hereinafter called "the Council") hereby agree to let an.....of.....
.....
("the hirer") hereby agrees to take on hire with option of purchase, as mentioned below and in the conditions, at a rent of.....
per.....payable in advance.....
hereinafter called "the fittings") for the term of two years from the .....day of.....191.....for use on the premises occupied by the hirer at the above address upon the conditions printed on the back hereof, and the hirer hereby agrees to pay regularly and punctually the said rent in advance on.....in each..... during the said term.

The hirer has paid, or will forthwith pay, to the Council £..... ("the deposit") for the option to purchase the fittings at the price of £.....and upon the terms set forth in the said conditions.

The Council and the hirer agree to perform and observe the said conditions.

Dated this.....day of.....191.....

Signed on behalf of the Council .....
Town Clerk or General Manager.

Signature of hirer.....

Witness.....

Quotation dated.....

6d. Stamp.

Consent to be signed by landlord where consumer is only occupier.

I.....the landlord of the above-named consumer, and owner (or lessee for an unexpired term of..... years) of the said premises, consent to the installation of wires and fittings in the said premises, upon the terms and conditions of the above agreement to be entered into by the consumer.

Landlord's signature .....

Address.....

Dated this.....day of.....191

CONDITIONS.

1. The consumer has the option, subject to condition 7, exercisable at any time during the hiring (unless this term of two years mentioned in the agreement shall have been previously determined under condition 7), of purchasing the fittings at the price of £..... (hereinafter called "the price") in which event credit shall be given to the consumer for the deposit and the amounts paid by way of rent. The deposit will belong to the Council if the option is not exercised or the agreement determined under condition 7.

2. The consumer may exercise the option by giving notice in writing to the Council, and paying to the Council such sum as together with the deposit and the amounts paid by way of rent will amount to the price.

3. When the consumer shall have exercised the option and paid the price, the fittings shall remain the absolute property of the Council.

4. The consumer shall, so long as the fittings remain the property of the Council, keep the same in good order and condition, and bear the cost of all necessary repairs and renewals, including damage by fire, unless otherwise agreed, but all repairs and renewals in connection with the fittings shall be effected at the consumer's cost by the Council's servants or (at the option of the Council) by a person approved by the Council. The consumer shall forthwith give notice to the Council of any breakdown, accident, or damage of or to the fittings. The consumer shall also, so long as the fittings remain the property of the Council, keep the same insured against loss or damage to the amount of the price, in the joint names of the consumer and the Council.

5. So long as the fittings remain the property of the Council, the Council's servants shall be entitled, at all reasonable times, to enter the said premises for the purpose of inspecting the fittings, and or effecting any repairs or renewals.

6. So long as the fittings remain the property of the Council the consumer shall not sell the fittings or any part thereof, from the premises mentioned in the agreement, or make any disposition on hire, charge, or in anywise deal with the same, and the Council's name or brand shall not on any account be removed from the fittings, or any part thereof, defaced or obliterated.

7. The Council shall at any time during the said term, or while the fittings remain the property of the Council—

1. Fail to observe and perform any term or condition of this agreement, or
2. Fail to pay any instalment of rent for seven days after the same has become due, or
3. Be adjudicated a bankrupt, or file a petition in bankruptcy against himself, or have a receiving order made against him, or make any composition or arrangement with his creditors, or any of them, or commit any act of bankruptcy, or be ordered to be wound up, or
4. Execute or create any mortgage, incumbrance, or charge of or upon the premises upon which the fittings are placed, or grant any bill of sale upon his goods and chattels upon the said premises, or
5. Have any execution or distress to be levied on his premises, or
6. Cease during the said term to take from the Council all electrical energy required by him, or
7. Fail to pay for the electrical energy consumed within 14 days after demand.

the Council, or their agents on their behalf, forthwith to determine the hiring, but without prejudice to any right of the Council which shall have accrued, and the Council shall be entitled to enter upon the said premises, and take possession of and remove the fittings, and forthwith recover any sum then due, together with the reasonable expense of such removal.

8. An inspector of the Council shall supervise the erection and installation of the fittings, and test the fittings upon completion. A certificate by the inspector that the fittings have been tested by him, and have passed the necessary tests, shall be conclusive evidence, that the fittings have been properly erected and installed by the Council, and the Council shall not be liable for any loss or damage whatever, consequent upon any breakdown or failure of the fittings.

9. The consumer shall give to the general manager not less than one month's notice of his intention to remove from the said premises, and if such notice be duly given and the fittings be left in good order and repair, the benefit of this agreement and the deposit and all rental payments then made, may, with the consent of the Council, be transferred to the incoming tenant, on his undertaking the liabilities and obligations of the consumer hereunder.

10. Any notice or demand under this agreement shall be sufficiently served if sent to the consumer by prepaid registered letter addressed to him at the said premises.

Hire-purchase is a powerful argument when others fail, but the consumer has to be known; mortal offence may be given by broaching the subject to the wrong man or woman.

COOKERS.

I regard cookers and radiators as the future big business for domestic supply. Radiators are already in very wide use in London, due chiefly to the general reduction in the price of current. They are not of such value to a supply undertaking as cookers, because the latter are used all the year round, and mainly in summer, whereas radiators are not used at all in the height of summer, though the number of days of use per annum is much greater than is generally realised, as consumers find them exceedingly useful to put on in cold summer evenings and nights. Cookers will also be more generally used than radiators, because the cost is as low as gas at 1d. per unit, and the enormous hygienic advantages which electricity possesses over gas, in addition to the absence of poisonous fumes, heat and general nuisance, ensure that the future of electric cooking will be exceedingly great.

It is difficult to keep pace with the manufacturers, as most of our leading firms are now actively engaged in turning out complete cookers, and design after design is being placed on the market, and each is generally better than its predecessor.

There is no doubt in my mind that if the supply people wake up and institute suitable tariffs, remove irksome restrictions and organise business-getting departments, as there is certainly the tendency to do now, the makers of the apparatus will not be found behind at their end. But makers cannot turn out cookers while supply people put all the difficulties they can think of in the way, and do not exert themselves to educate their consumers into electric cooking.

The splendid propaganda work being done by Mr. Berry puts all supply men under a deep obligation to him.

As soon as the demand arises the prices will tumble down, and *are* tumbling down. For instance, the best complete cooker I have yet seen is listed at under £12. What is needed is for supply undertakings to hire out cookers at a reasonable rate, even if at first the rate is not profitable. No new thing can be introduced on a profit-making basis immediately, and supply authorities must be prepared to lose at first on the hire.

Needless to say, none but the wealthy will buy electric cookers outright, any more than people will buy gas cookers, and we have got to make up our minds to adopt the same tactics as our gas competitors; in fact, as we know their struggles and difficulties in introducing gas cooking some years ago, we can start out on a more favourable basis.

An electric cooker must do all that a gas cooker will and more quickly. The old failures of electric cookers were due to too few watts being put in, which from the current consumption point of view was a most serious mistake. This is now rectified in modern makes, and we have not got the element trouble now which we had a few years ago.

A few points on electric cookers might be useful, the necessity for which has been ascertained from conversations between our business-getting staff and cooks and chefs. The hot plates require two or three heats, and should attain a temperature of from 600°F. to 650°F. to enable quick work to be done. I may say there are several suitable ones now on the market. The oven should be loaded to 2 kw. or 3 kw., and be preferably of a type in which the elements can be increased or decreased, or replaced by the consumers themselves. One is already available. The cooker circuits should be split up and taken to a separate switchboard and separate fuses, so calibrated that

Digitized by Google

one faulty circuit cannot possibly put the whole cooker out of commission, as this is fatal. Each circuit should have an illuminated sign showing up when it is turned on; this is a current saver.

Particular care must be given to the design of switches and fuses, and no switches should be fixed to the cooker itself; the connecting cables should be in metallic flexible tubing from the terminal box on the cooker to the switchboard, and all non-electrical metal effectively earthed. All parts of the cooker should be accessible for cleaning. The cooker should be so designed that it is never necessary to remove it for repairs. Replacements of elements or other parts where trouble can possibly arise should be easily renewable, if possible without the necessity for using tools, and from what I have seen of recent designs I do not regard this as altogether impossible; anyway, it is eminently desirable.

This may not appear to have much to do with the heading of the article, but we certainly cannot introduce cookers, which will be the most important of all domestic apparatus, unless they are satisfactory, and as we are paying a great deal of attention to electric cooking in St. Marylebone, our experience may be useful to some one.

The Business Instinct.

The best results in introducing domestic electrical appliances and increasing the output can only be obtained when, as I am happy to say is the case in St. Marylebone, the "business instinct" permeates the whole staff. Every section of the undertaking depends on the goodwill of the consumers, and present business can only be kept and new business obtained by recognising this fact.

Fortunately our accounts department is our own, and not in another (frequently quite unsympathetic) department, and it is audited quarterly by Messrs. Price, Waterhouse and annually by the L.G.B., which is about as complete a check as could be obtained, and from a new business point of view a self-contained department with its own accounts is an enormous advantage. It works closely with the mains and sales departments, and the business instinct goes all through each, resulting in courtesy and attention to consumers.

The following states our policy and our intentions, and that attitude is the only one which will result in a big extension of business with corresponding financial benefit to the undertaking as a whole. It is borrowed from a foreign electric supply undertaking.

COMPLAINTS.

It used to be good form in the public-supply business to ignore the word "complaint." The word had an unpleasant sound to managerial ears. "Information desk," "Adjustment bureau," or "Department of claims," were among the terms favoured, and every effort was made to minimise the fact that the department ever received such a thing as a protest from one of our 8,000 consumers.

Times change and so do customers. We do not like the word complaint any better than you do, but we are frank to admit that in a business as large as ours some mistakes will happen and some imperfections occur. We know that you realise this, and will consider the manner in which we rectify errors, rather than the error itself.

We guard against defects and strive to prevent them to the best of our ability. When things go wrong with the electric service, we prefer to have you tell us immediately and give us a chance to straighten them out, instead of cherishing a grudge against us and telling your neighbours about it.

An overcharge or a delayed connection may be due to no conscious fault of ours, but the spirit in which we correct the mistake is the criterion by which you should judge our professed determination to render good service.

Our employés are instructed to be as polite and willing to repair grievances as the management itself, and we believe, as a body, that they are. If, however, one makes a slip and temporarily forgets his duties to the public, you cannot possibly regret it any more than we do.

The uninitiated person will scoff at such a leaflet. Well, I am quite content to let him scoff in his ignorance. I know this, however, that such an attitude as indicated in the leaflet is a business-keeper and getter, and is a distinct financial asset to the undertaking.

THE SOUTHWICK POWER STATION OF THE BRIGHTON CORPORATION.

The system of electricity supply at Brighton was one of the earliest installed, and the progress of the undertaking from comparatively small proportions to its present position as one of the largest of the municipal stations in the kingdom testifies to the ability and resource displayed in its management. We have dealt with the growth of the system in our columns from time to time, so that our readers have been kept acquainted with the alterations and extensions made. The most important step taken in the history of the scheme was the erection of the turbo-electric plant at Southwick and the gradual substitution, by the supply from this plant, of that given by the Willans units initially installed at North road, which was the original electrical centre of the Brighton network. This last-named station still stands, but is used to house the plant which receives and converts the energy transmitted from the South-

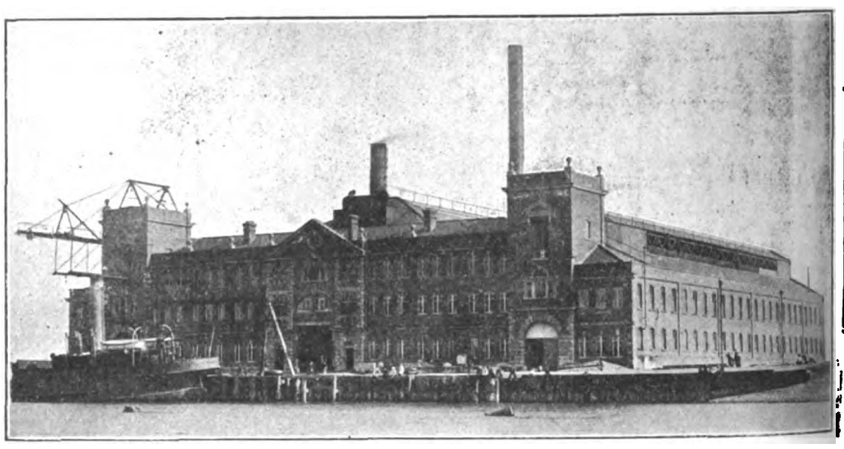

Fig. 1.—Exterior of Southwick Power House.

wick power house. An exterior view of this station is shown in Fig. 1. Since our description of the station (*see* The Electrician, Vol. LVII., p. 326) a large turbo-generator of 3,500-4,000 kw. capacity has been added. This plant is the combined product of Messrs. Richardsons, Westgarth and Siemens Bros. Dynamo Works, who supplied the turbine and generator respectively. This interesting unit may be seen in the background of the view of the station in Fig. 2, the last plant from the end. The turbine is of the two-cylinder Parsons type, and has been built to the designs of Messrs. Brown, Boveri & Co. It was selected because of its higher efficiency as compared with either the impulse or single cylinder reaction types. This type of turbine has been extensively adopted both in this country and on the Continent. There is a 6,250 kw. set of this pattern at the Dunston power station of the Newcastle-on-Tyne Electric Supply Co.

The two-cylinder turbine allows greater economy to be obtained by increasing the number of rows of blades without increasing the distance between bearings. In the single-cylinder type the larger pressure drop per row of blades necessitates a higher blade velocity and therefore a larger diameter of drum. This larger diameter reduces the blade height and increases the leakage loss by increasing the ratio of radial clearance to blade height. In the two-cylinder turbine, having a smaller pressure drop per row of blades, the velocity of the blades and therefore the diameter of drum may both be reduced. This admits of a greater blade height with a reduced clearance ratio, and results in a considerably improved steam consump-

Digitized by Google

tion. The low-pressure portion of a Parsons turbine is generally admitted to be extremely economical, but it has always been stated that the high-pressure end has a much lower efficiency than the low-pressure end.

The high-pressure drum is of uniform diameter, and therefore is free from distortion troubles. The steam pressure at the inlet to the low-pressure cylinder does not exceed approximately 50 lb. per square inch, so that the low-pressure cylinder

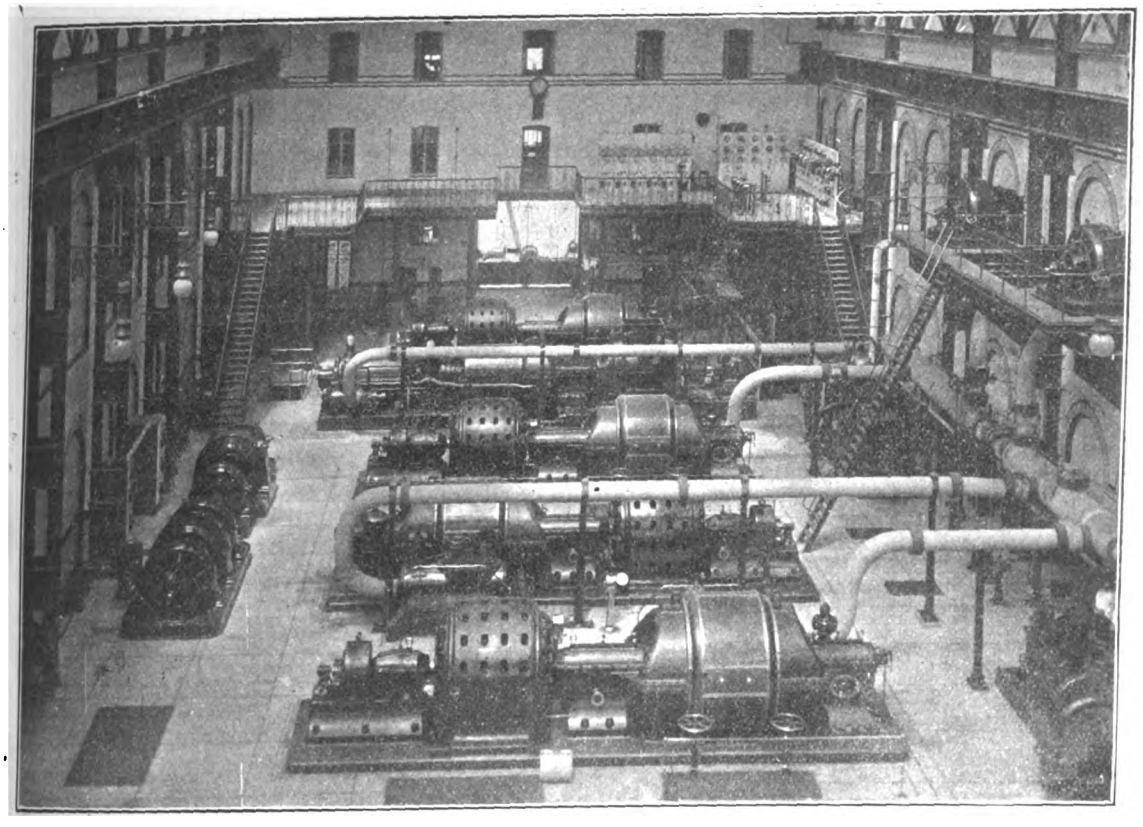

FIG. 2.—GENERAL VIEW OF ENGINE ROOM, SOUTHWICK.
The new 3,500 kw. set is the last but one from the far end.

is not subjected to any high temperatures. At the low-pressure end the rows of blades have been increased considerably as compared with the single-cylinder type and the efficiency of this portion is still further improved. Owing to the lower steam and blade velocities than in the impulse type, the

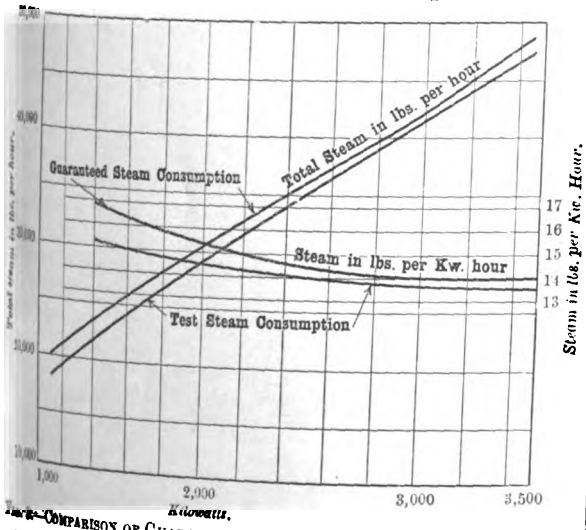

FIG. 3.—COMPARISON OF GUARANTEED AND ACTUAL STEAM CONSUMPTION.
3,500 kw. 1,500 R.P.M., steam pressure 180 lbs. sq. in. Temp. 530°F. Vacuum 28½ in. Barometer 30 in.

original efficiency of the turbo is maintained over a long period. Steam is admitted to the turbine through a double-beat valve controlled by the governor through an oil relay. The gear consists of a double-beat valve actuated by the spring-loaded piston, which is under control of the oil under pressure entering from the main lubricating system. The controlling pressure of the oil is determined by the vertical position of a sleeve and a spring-controlled governor. If the speed increases the governor lowers the position of the sleeve, thus increasing the outlet area of the oil pipe, which diminishes the pressure of the oil under the piston, resulting in a corresponding closing of the double-beat inlet valve. When the speed of the turbine decreases, the position of the sleeve is raised, whereby the exit area of the oil pipe is decreased with the opposite result. The oscillating movement of the valve, which practice has shown to be an advantage for close governing, in that all moving parts of the gear are kept in constant motion, is obtained by the very simple device of making the upper governing edge of the rotating sleeve at an angle with the axis. The exit area of the oil pipe is thus varied slightly once in a revolution of the shaft, with the result that a tremor is produced in the valve and its piston and rod, which is in synchronism with the revolutions of the shaft. Thus, the undesirable wavelike fluctuations in the steam pressure produced by the ordinary oscillating motion are avoided.

The guaranteed steam consumption of this set are given below, the conditions being 180 lb. steam pressure, superheat to 530°F., and a vacuum of 28·25 in.

3,750 kw.	14·2 lb. per kw.-hour.
3,500 kw.	14·0 ,, ,,
3,000 kw.	14·0 ,, ,,
2,250 kw.	14·9 ,, ,,
1,500 kw.	16·5 ,, ,,

Preliminary trials were taken recently, and the results reduced to guarantee conditions are shown by permission of Mr. Christie in Fig. 3, where the guarantees are also plotted. One test result was as follows:—

Load	3,550 kw.
Pressure	200 lb. per sq. inch.
Temperature	523°F.
Vacuum	28·46 in.
Consumption	13·0 lb. per kw.-hour.

Digitized by Google

The condensing plant was made by the turbine builders, and is of their standard contraflo type, fitted with a vacuum augmentor and Edwards air pumps. The condenser has a cooling surface of 5,000 sq. ft., and is guaranteed to maintain a vacuum of 28·25 in. when dealing with 53,500 lb. of steam per hour and supplied with 6,000 gallons of water per minute at 70°F. During the turbine tests the water temperature was 63°F., and a vacuum of 28·25 in. was maintained without using the augmentor. A general view of the machine from the turbine end is given in Fig. 4.

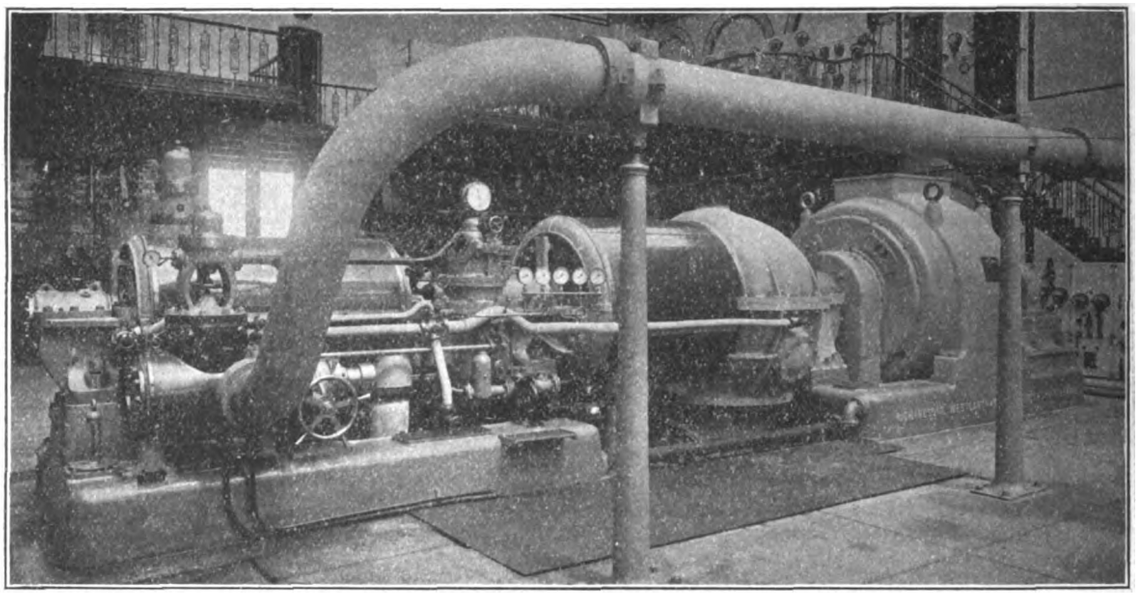

FIG. 4.—VIEW OF 3,500 KW. TURBO-GENERATOR FROM THE TURBINE END.

The generator of this large unit has a normal output of 3,000 kw. at 0·85 power factor. It delivers three-phase 50-cycle current at 8,000 volts when running at a speed of 1,500 revs. per min. The temperature rise after a continuous 3 hours' full load run, with the addition of 25 per cent. overload for 1 hour, was guaranteed not to exceed 75°F.; with the same period at full-load and the addition of 15 minutes at 50 per cent. overload the temperature rise was to be the same as the above.

The general construction of the machine follows the standard practice of the firm. Fan cooling has been adopted with a totally-enclosed stator frame. The cool air enters at the lower part of the machine, which is in the basement of the engine-room. This air is passed through a filter of the vertical screen type, made by the Buffalo Forge Co.; after passing through the windings of the machine under the action of the fan fixed at one end of the rotor heated air is discharged through an aperture at the top of the stator frame. Both stator and rotor are ventilated on Siemens' patent axial system, which provides for the passage of air through the active iron in a direct parallel to the machine shaft. The ends of the stator and rotor which are furthest removed from the air intake are naturally the hottest parts of the machine, and these are immediately accessible to a thermometer. A second fan is provided for drawing cool air through the rotor.

The stator slots are of the partially closed type, and the coils are pulled through, being subsequently supported on substantial end brackets. The rotor is provided with a distributed winding which is carried in equidistant open slots closed by metal wedges. The end connections are held down by four steel winding covers machined inside and out, and registered at either end on machined surfaces. The slip rings are of steel, and copper carbon brushes are used.

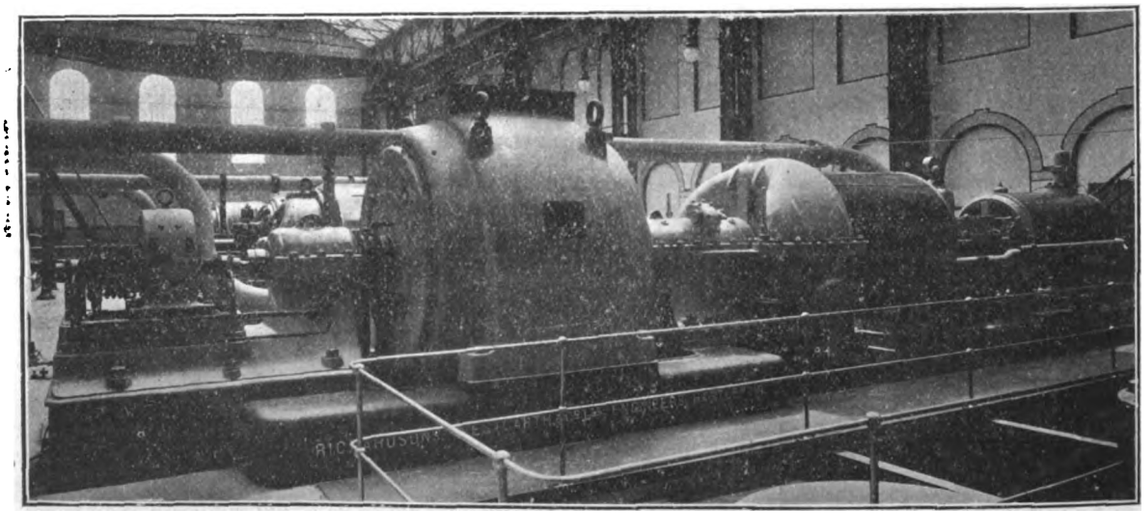

FIG. 5.—GENERAL VIEW OF 3,500 KW. TURBO GENERATOR.

The exciter is connected to the turbo-generator shaft through a flexible coupling, and it rests on its own bedplate, bearings being mounted on an extension of the turbine bed. Fig. 5 shows a view of this interesting set taken from the north end of the station.

The induced draught plant at the station consists of three large

Digitized by Google

"Ulster" fans, made by Musgrave & Co., Belfast. Each fan is capable of effecting the combustion of about 20,000 lb. of coal per hour, and at the same time of maintaining a suction at the fan inlet up to 3 in. water pressure. The fans are driven by direct-coupled variable speed direct-current Westinghouse motors. The arrangement of the induced draught plant is exceptionally practical, the fans themselves being erected in the boiler house, and the shafts carried through the wall to the adjacent engine house. The motors driving the fans are

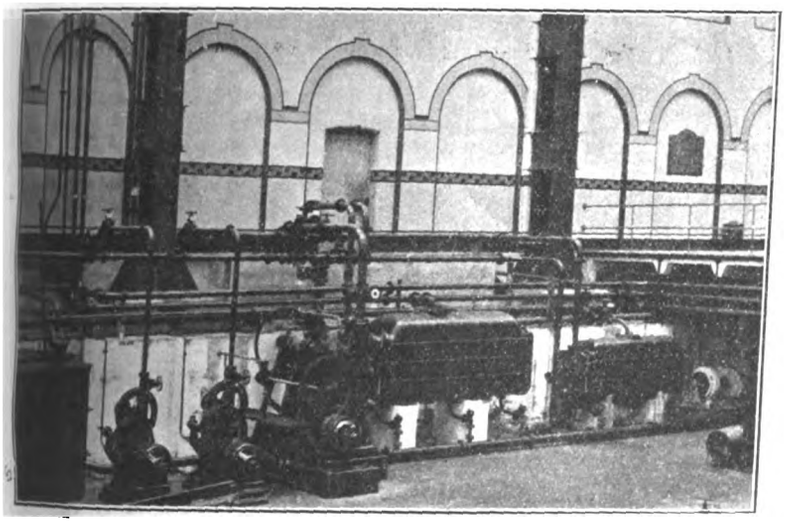

FIG. 6.—GENERAL VIEW OF OIL SYSTEM.
The oil coolers are on the right.

fixed on specially designed platforms in the engine house, having access by iron stairs from the floor.

The fans and all their fittings are of rigid construction, the cases being built of $\frac{5}{16}$ in. steel plate. Special attention was also paid to the bearings, which are of the ring lubrication self-aligning type. Unusually large connections are fitted to allow of a large volume of cooling water in the jackets in case of the gases being exceptionally high in temperature when the economisers are not in use. The gases are discharged directly from the fans into two steel chimneys.

One of the most interesting features of the plant at Southwick is the oil supply system for the bearings of the turbines and generators. In many turbine stations the oil is supplied to the bearings at a comparatively high temperature, and some difficulty is experienced in keeping the bearings cool. With a view to permanently obviating this, Mr. Christie has put into operation a system of oil supply in which a constant flow to the turbines is always assured and, what is equally important, the oil is filtered and cooled. By the two last-named processes it is possible to utilise the same oil again, and Mr. Christie has succeeded in maintaining a constant circulation of oil through a practically closed system. In this respect we believe the system at Southwick to be unique, and on that account it is worthy of detailed description.

In the whole system there are about 6,000 gallons of oil constantly circulating. Situated at a height of 40 ft. above the engine-room floor are two tanks which hold about 1,500 gallons of oil each. From these tanks the oil flows by gravity to the turbine bearings, whence it falls a further 10 ft. to the level of the filters in the basement. The oil flows over weirs in these filters after passing through a number of layers of filtering cloth. The filters are so constructed that sections can be shut off for the removal of the sediment, though this is only necessary at infrequent intervals. Arrived at its lowest level the oil is forced through cooling condensers into the roof tank by pumps. The coolers are two in number and were originally in use at the North-road station when the steam plant was running there. One cooler is of 3,000 to 4,000 sq. ft. surface, and the other 2,000 sq. ft. The cooling medium is sea water, which is circulated through the condensers by centrifugal pumps driven direct by 3 H.P. motors. The oil pumps are of the three-throw type, gear-driven by motors. There is one of 8,000 gallons per hour capacity driven by a 5 H.P. motor, and two of 4,000 gallons per hour capacity, each driven by a 3 H.P. motor. The large pump is run on the day load, and one of the small ones at night. A stand-by to these pumps is provided by two Worthington steam pumps each of 5,000 gallons per hour capacity. In the adjoining illustrations the general lay-out of this plant is clearly shown. A striking testimony to the efficiency of the system is afforded by the fact that Mr. Christie has been able to add quite new oil to the old with absolute impunity when making up the small loss in the system. The original oil has been in use over six years. The temperature at which the oil enters the works is during the summer about 85°F., and in the winter about 60°F. It will leave the works at 75°F. in the summer and proportionately lower in the winter. By this comparatively simple arrangement of plant the oil cost is kept at a low figure; but what is of prime importance, the bearings are maintained in good condition, and there is practically no danger of overheating. Mr. Christie is to be complimented on the installation and operation of such a unique system. Figs. 6 and 7 are a view of the complete oil system and a near view of the oil pumps respectively.

The latest pattern of Lea recorder is installed at the station, the notch tank being placed in the basement of the engine-room near the hot well. The recording instrument is mounted on a level with the engine-room floor, where it can be easily read. The arrangement of the air-pump discharge pipe is such that the water from any one turbine can be turned through the recorder, or the total of several machines running can be measured. The apparatus, which was installed by the Lea Recorder Co., Deansgate, Manchester, has a maximum capacity of 150,000 lb. of water per hour, through a half 90 deg. V-notch. The instrument has a stroke of 9 in., and is of the indicating, recording and counting type. We understand that the instrument is

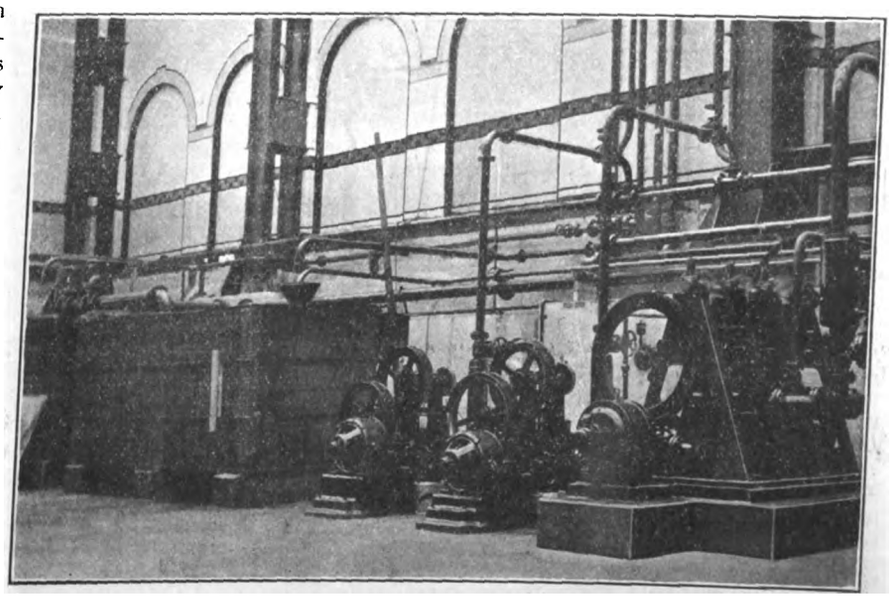

FIG. 7.—NEAR VIEW OF OIL PUMPS, WITH FILTER IN BACKGROUND.

Digitized by Google

invaluable to the station staff in the preparation of the cost records of the running of the station.

Not the least interesting piece of work carried out in the station, and by Mr. Christie and his assistants, was the removal from the engine-room of the solenoid-operated 8,000-volt three-phase switches, which were originally installed under the operating gallery at the north end. This location was found to be unsuitable, and the whole of the machine and feeder switches have been transferred in two storeys into that portion of the building which was once a number of offices. This piece of engineering work, including as it did the rearrangement of the extra high-tension conductors and all the control leads, was carried through with complete success without a single interruption of the supply. Only those engineers who have undertaken a similar task will appreciate the difficulties encountered and the resourceful methods needed to overcome them. As at present arranged, on the cubicle system in a fireproof and damp-proof structure, the switchgear is regarded as a stable adjunct to the generating plant. The work referred to also involved the re-grouping of the control panels on the operating gallery, and the new scheme leaves the back of these panels clear of high-tension gear of any kind.

The plant at the North-road station, now used as a sub-station, comprises rotary converting plant aggregating 6,380 kw. capacity. An interior view of this station is shown

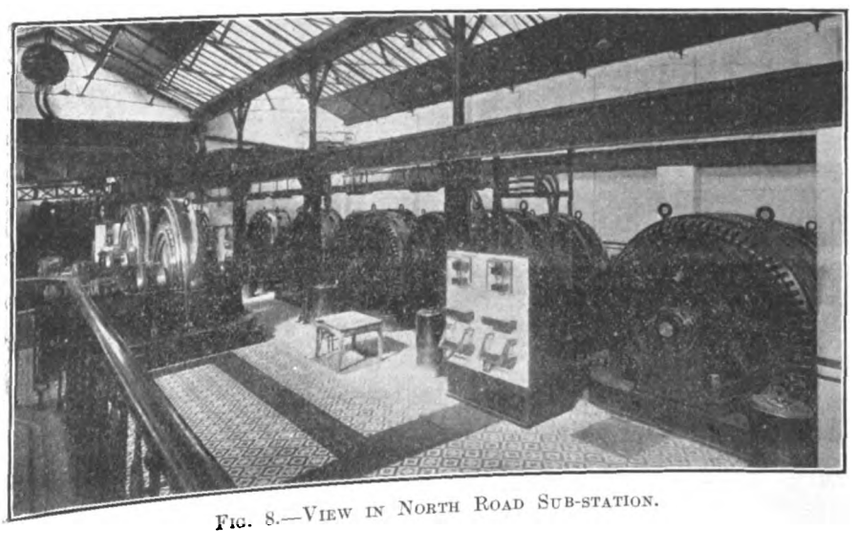

Fig. 8.—View in North Road Sub-station.

in Fig. 8. Two 1,500 kw. rotary converters are included in the plant, and the rest of the machines are induction motor-generators. The 500 kw. E.C.C. generators, which were originally driven by Willans engines, are being removed from their bed-plates in pairs and coupled to a 1,300 H.P. induction motor for use as motor-generators. Two pairs of these units have been converted in this manner.

SOME ELECTRICITY CONSUMERS OF THE BRIGHTON CORPORATION.

Although Brighton is not essentially a manufacturing centre, there are many industrial concerns in the town which require power for the operation of their machinery. The largest consumer on the network is at present the L.B. & S.C. Railway Co., who drive the whole of their railway workshops by electric power. This customer has come over gradually on to the supply by a process in which the steam engines formerly used have been superseded by electric motors. In these works the Company's locomotives are built and tested, and the machine-tool equipment is of an extensive character. A supply is given at 230 volts, the Corporation feeders being looped in and out to a large central switchboard. A considerable number of motors are installed, and these are all of the shunt-wound fixed-speed type. The majority were supplied by the General Electric Co. The driving is on both the individual and group systems. Four general sizes of motors are in use, these having an output of 5, 10, 15 and 30 H.P. The motors have been placed in the most convenient positions for belting or gearing up to the line shafting, and in the case of the latter they are bolted up to the columns supporting the roof, and the drive is by helical gear. The shops, in accordance with the practice of all railway engineering works, are fitted out with a fine equipment of electric travelling cranes. These are of the three-motor type, and in one or two cases are conversions from rope drive. The capacities range from 30 cwt. to 35 tons, and the longest span is 53 ft. 6 in. In the boiler shop there are four cranes of 40 ft. span, two of 20-ton capacity and two of 12-ton capacity. The 15-ton crane in the riveting shop runs at a height of 41 ft. from the ground, and is operated from the floor level by a tramway-type controller. In the frame shop there is a jigger crane to carry material from the well of the shop into the galleries on each side, or vice versa. In connection with this crane there is an automatic device for closing and opening the gates on the galleries to ensure that no one will walk through after the crane has passed. The cranes have been built by Messrs. Craven Bros. & Vaughan & Son, and the motors are respectively Lancashire Dynamo and Hall.

A most interesting crane is one in which a battery of accumulators is used for operating the motors. This is a 5-ton bascule crane by Craven Bros., and is illustrated in Fig. 1. The travelling motor is 8½ H.P., and is bevel-geared to the rail wheels. The hoist motor is 5¼ H.P. and the slewing motor 4 H.P. All these motors are Lancashire Dynamo, and are totally enclosed. The crane has a sweep of 17 ft. 6 in. and a lift of 14 ft. 6 in. at the long end. The battery is capable of operating the crane at full load for a period of 1 hour.

A number of large motors are in use in the works, the maximum horse-power being 70. Two Hall motors of this type are shown in Fig. 2 direct coupled to air compressors and running at 225 revs. per min. Another 70 H.P. motor drives a line shaft and another is in operation driving the deep well three-throw pumps which raise water for the works from the level of 160 ft. Another 70 H.P. motor drives a 40 in. Sirocco fan drawing off the smoke from the smiths' fires, which are of the down draught pattern. This type of fire was adopted in order to allow a clear overhead runway for the crane from the smiths' shop into the smiths' yard. A number of 30 H.P. motors are in use driving machine tools. One of these operates a 23 ft. planer, the drive being through Mitchell gear. A large set of vertical rolls in the boiler shop is driven by a motor of this size, and there are also two more of the same output operating the force pumps for the hydraulic accumulators and riveting plant. The main feeders into the works are of 1 sq. in. section, and the energy consumed for a year is in the neighbourhood of 1,500,000 units. The entire equipment is on modern lines, and engineers interested in machine-shop driving should take an opportunity of obtaining permission to view the works. We ourselves are indebted to the management for facilities to inspect the shops and take photographs, and particularly to Mr. Field for his courtesy in the supply of the foregoing particulars.

Another interesting plant is that installed in the Britannia Flour Mills, Southwick, where an old steam-drive was replaced by a number of electric motors. One machine has been erected so as to drive by ropes on to the pulley formerly driven by the steam engine. The supply is at 460 volts, and is given by the auxiliary rotary converting plant at Southwick station, which is just across the harbour. The same mains also supply the local district of Aldrington.

The Britannia Mill is the property of Messrs. C. R. Smith & Sons, and it is mainly through the foresight and enterprise of Mr. Richard Smith that the installation was carried out. The electric power plant includes two "Reform" motors, switch-

Digitized by Google

board and control pillars. One motor with an output of 150 B.H.P. at a speed of 220 revs. per min. was required to drive the mill and wheat cleaning plants, and the other motors were installed to drive the machinery in the silo. The steam engine which ran at a speed of 64 revs. per min., was dismantled and the large motor erected in its place, the switchboard and starter being fixed alongside, thereby allowing convenient control. Fig. 3 shows this motor in position.

The water for washing the wheat is raised from a borehole below the engine-room by a three-throw ram pump driven direct from the motor shaft. To obviate extensive alterations and to bring the actual stoppage to as few days as possible, it was essential that the existing drives should be interfered with

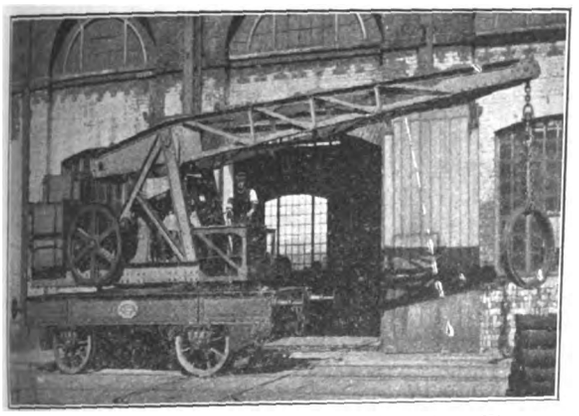

FIG. 1.—5-TON BASCULE CRANE IN L.B. & S.C. RLY. WORKS.

no more than was absolutely necessary. Thus, the large motor shaft was extended through the wall into the existing rope race of the mill where a rope pulley with third bearing was provided to receive the existing drives. The great advantage of having a separate motor for the silo is that the intake plant may be run independently of the mill.

The advantages which the use of electricity has brought about in this case are many. The storage capacity, which was previously insufficient, has now been increased by the use of the old boiler house. Considerable floor space has also been saved in the mill, as the motor requires but half of the space originally occupied by the engine alone. Speed troubles are

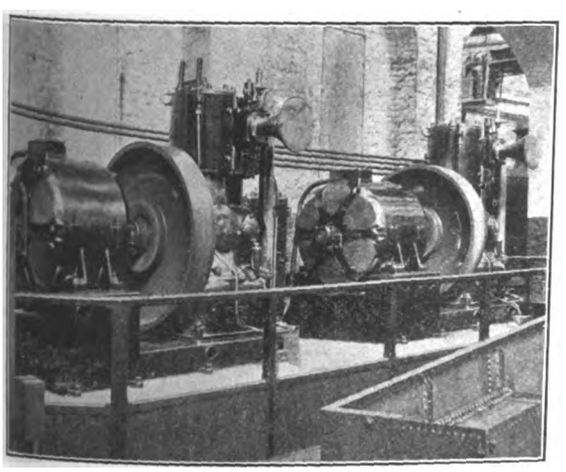

FIG. 2.—TWO 70 H.P. MOTORS DRIVING AIR COMPRESSORS, L.B. & S.C. RLY. WORKS.

a thing of the past, uniform turning motion is assured, noise is eliminated, easier starting could not be desired, and cleanliness reigns supreme. The air around the mill is no longer defiled by the smoke from the boilers, and inside the mill smut troubles have ceased. The whole of the work in connection with the installation was carried out by Henry Simon (Ltd.), Manchester, the well-known milling engineers, to whom we express our thanks for the above details.

The electricity department is always keen on opportunities for power supply. For instance, last winter the landing stage at the head of the West Pier was carried away during a gale, and the work of reconstruction is now in progress. A small machine shop has been fitted up, and the hack-saws, drills and grindstones are driven by a 10 H.P. motor. A number of portable electric drills for holes up to ⅞ in. are also used on the girders *in situ*. This equipment though small is invaluable to the engineers carrying out the work.

On the Palace Pier an important extension is in progress at the shore end. A large winter garden and pavilion is being erected, and when finished this will hold 2,000 people. The same general scheme of illuminations which are a permanent feature of the pier will be embodied in equipping this new piece of work.

The pile-driving for this extension is also being done by electric power. There is a 10 H.P. motor geared to a special winch, which is employed for the purpose of turning the head of the pile during the process of screwing it into the shingle and sand. The piles are of interest because they have enabled the extension work to be done expeditiously and with certainty, the type of pile having withstood the test of the severe gales which are experienced on the South coast.

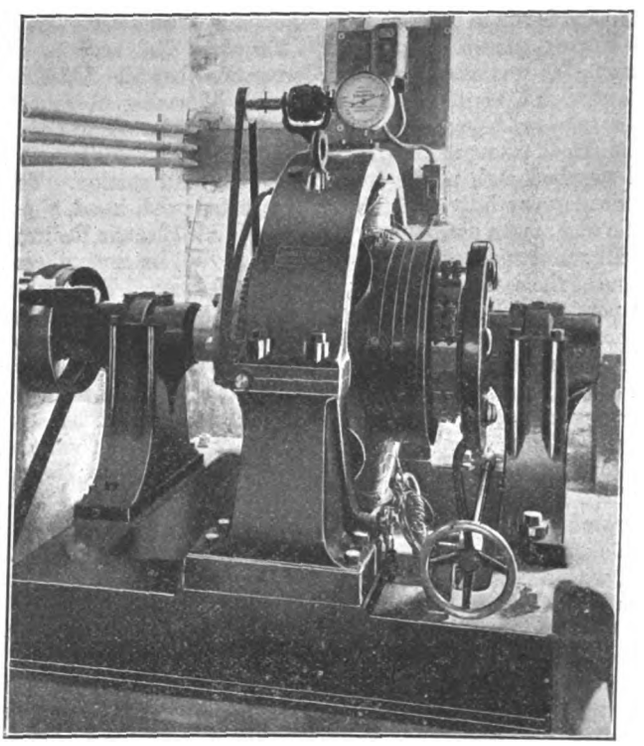

FIG. 3.—150 H.P. MOTOR DRIVING BRITANNIA FLOUR MILLS, SOUTHWICK.

At the sea end of the pier the Pavilion and Theatre have been practically remodelled. The management are most enterprising in bringing the pier well up-to-date, and have erected a spacious tea garden on the roof of the pavilion in addition to a large enclosed dining-room which overlooks the sea and is illuminated by Holophane bowls. The generally ornate design of the new building has been surmounted by minarets after the Moorish model. The entire structure is outlined by hundreds of electric lamps, and soft and pleasing effects have been produced. To encourage the use of the roof garden and add to the comfort of the public, two electric lifts have been installed on the east and west sides of the pavilion.

That the management are keenly alive to the value of electricity is shown not only by the foregoing, but more particularly by the fact that they have recently installed an electric oven and a number of large electrically-heated utensils. These are being used in the large kitchen which is needed for the extensive cuisine in connection with the dining saloon and tea garden. This apparatus is supplied from the ordinary network on the pier. It is of Prometheus manufacture, and is of the latest pattern.

For many years past the main and side streets in Brighton

Digitized by Google

have been lighted by electric lamps. The three miles of sea front is brilliantly illuminated by as fine a row of open type arc lamps as can be seen in Europe. There are 372 arc lamps altogether, and in addition 178 public building lamps are supplied and maintained. The side street lamps are attached to the gas posts and are in lanterns of the same pattern. The original lighting was by carbon lamps, two in series on 240 volts. There are now in use 55-watt "Onewatt" lamps, burning singly at 240 volts, one in each lantern. Upwards of 2,000 posts have been fitted with these lamps. We understand that these lamps have an average efficiency of 1·25 watts per candle, and that they have proved eminently satisfactory on the score of life and ability to resist vibration. The filament of the lamp is of drawn tungsten.

Judging by the amount of illumination material which has been erected, Brighton is determined to keep up its reputation as "London-on-Sea." The Corporation have carried out an ambitious scheme in the lighting of the front, and have erected a continuous length of festoons between the arc lamp pillars. We understand that in the three miles of front some four miles of "strip" have been used. With the lamps at 1 ft. centres this means a total of 21,120 holders and lamps. Each lamp is of 5 c.p., and is run in parallel across the 230-volt network. There are feeding points about every 200 yds. The scheme of illumination was erected for the Coronation, but the I.M.E.A. delegates will be given an opportunity of seeing it, as the decorations are being left up for a month after the celebration.

The local tramways are, of course, run by the Corporation and supplied with power from the North-road station. The district is very hilly and the cars are fitted with hand, rheostatic and mechanical slipper brakes. Volk's Electric Railway is still running along the East front, and will be remembered as one of the earliest attempts at electric traction. The undersea portion at Rottingdean, over which a special elevated car ran for a time, has been disused since it was destroyed by a gale. The local motor-bus company has in service a fleet of electric omnibuses, and the battery charging plant is supplied from the ordinary network. An interesting arrangement of boosters is in use for the charging of each battery at its own voltage. Visitors will be given an opportunity of inspecting this plant.

The foregoing description gives an idea of the supply system operated by the Corporation, and will serve to show the extensive character of the electric service in Brighton. Needless to say, with a gas company supplying in the area the competition between the two systems is exceptionally keen. In fact, it accounts in no small measure for the progress which electricity has made.

In concluding this and the foregoing article we must express our thanks to Mr. Christie for the facilities which he has afforded us in collecting the information and for taking photographs at Southwick; to Mr. J. Cleary, the consumers' engineer, we are also much indebted for assistance.

LIGHT AND SHADE IN INDIRECT LIGHTING.

BY JUSTUS ECK, M.A.

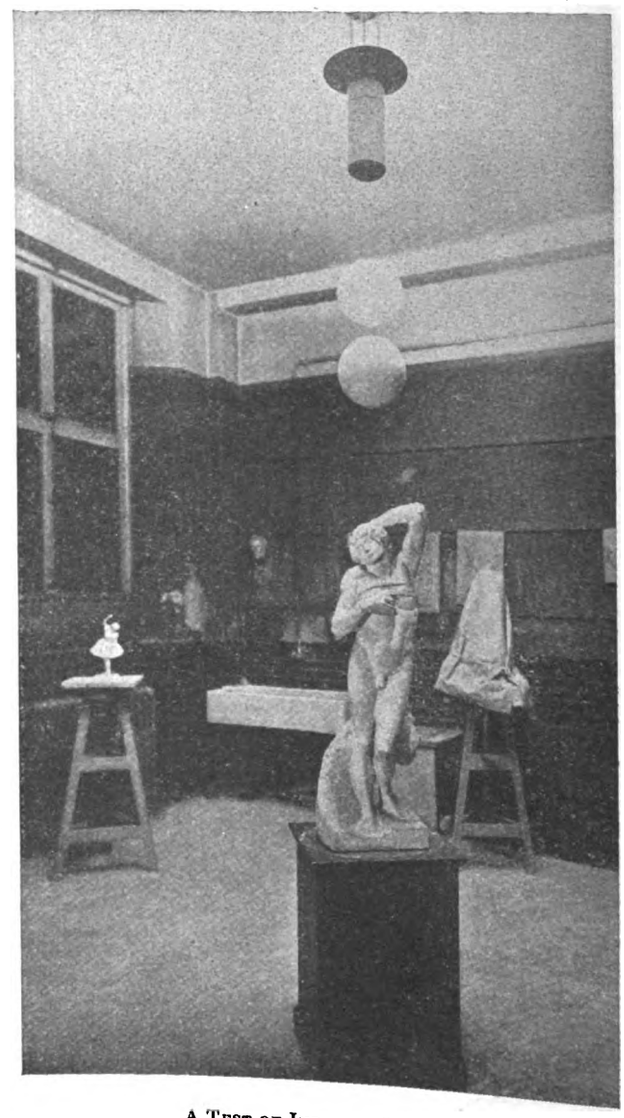
Summary.—The author controverts the view that indirect lighting gives an illumination that fails to give proper light and shade effects, and he supports his opinion by measurements taken in a room illuminated by an inverted arc lamp.

The question of the possibility or otherwise of securing correct light and shade effects in indirect lighting is at the moment receiving considerable attention from illuminating engineers.

Statements have recently been made at meetings of the Illuminating Engineering Society (London) and in the electrical press, as to the difficulty of obtaining by the use of such lighting those correct shadow values by which alone satisfactory relief can be secured, and upon the presence and correct values of which depends the ability of the eye to perceive and discriminate form, *i.e.*, to *see*.

Such statements are often dependent upon the assumption of conditions more or less impossible of attainment in practice; are rarely, if ever, accompanied by any data as to the dimensions of the rooms, the nature of the light sources, the size and type of reflector used, the colour values of the decorative scheme, or the character, colour and diffusion of the light itself, and whilst therefore very liable to prove misleading by reason of their incompleteness, are of little or no value in serious work.

In a recent article in THE ELECTRICIAN on the "Nomenclature of Primary and Secondary Sources of Light"* the author, a well-known electrical engineer, first pre-supposes abnormal conditions, thereafter proceeds to deduce results quite contrary to those usually obtained in practice, and finally, and as a result, condemns (by implication) indirect lighting as failing to give



A TEST OF INDIRECT LIGHTING.

sufficient relief and as unsuitable for the illumination of monochromatic objects, such as, for instance, statuary. The article in question possesses, however, one meritorious feature of considerable value, quite apart from its primary object, in that the author therein lays down certain definite conditions and suggests an experiment which has given rise to an investigation by the present writer which has led to results of peculiar interest to all illuminating engineers, and will doubtless stimulate research in others.

A room is assumed in which the walls, ceiling and floor all have a high-reflecting efficiency, and the statement is made that if, in the centre of that room is placed a single light source,

* THE ELECTRICIAN, May 26, 1911, p. 262.

Digitized by Google

and below this, but protected from the direct rays, is suspended a small sphere, the latter will not to the human vision appear spherical however highly it is illuminated. It is not usually possible to place the light source in the centre of a room, *i.e.*, equi-distant between the floor and the ceiling, as well as equi-distant from the four walls; and, even were it possible, it would in practice be found exceedingly inconvenient in a room, for instance, 12 ft. high, to place the light source at a height of 6 ft. It is not usually possible to secure a sufficiently high and sufficiently even coefficient of reflection for ceiling, walls *and floor*, and it is difficult in practice to eliminate such items as pictures, doors, cupboards, &c.

Most rooms are provided with windows in one or more of the walls, which, unless provided with blinds tinted to exactly match the colouring of the walls and drawn whenever the artificial light is used, quite upset the balance of reflection, and even in those rooms in which windows are absent, and both ceiling and walls are white-washed, the reflecting value of the floor surface is usually sufficiently lower than that of the walls and ceiling to ensure the retention of the rotundity of the sphere.

Further, it will be found by anyone caring to repeat the experiment that even in a room minus windows, and in which the floor is tinted to correspond with the walls and ceiling, sufficient relief remains to render the sphere quite distinguishable visually, although under such circumstances a photographic representation cannot readily be secured; so that unless the sphere were so small as to be practically devoid of surface, or the room were itself spherical in form, it would apparently never present to the normal eye the appearance of a perfectly flat disc.

Turning now to the consideration of the question as it applies to actual installations used under normal conditions, the photograph reproduced shows the result of the suggested experiment performed in a room specially chosen because of its close approach to the assumed conditions by reason of the somewhat unusual character of its floor surface referred to later.

The room stands north-east-by-east, measures 22 ft. 9 in. by 20 ft. 2 in., and has a height of 13 ft. 8 in. from floor to ceiling. It is lighted during the day by two windows on the east side having an aggregate area of 51·6 sq. ft. and giving a ratio of window surface to floor surface of 0·112 to 1, from which it will be appreciated that the lighting is quite up to the average. The nature, colouring and surface brightness in foot-candles of the various surfaces, as measured by the Holophane Lumeter during clear bright weather at 3:30 p.m. on June 6, 1911, were as follows:—

Daylight Tests.

Position.	Nature of surface.	Surface brightness (foot-candles.)		
		Average.	Max.	Min.
Wall dado filling	A. Light brown glazed bricks	4·03	8·2	0·72
Wall above dado	B. Light greenish grey distempered plaster matt.....	4·2	5·6	2·6
Frieze and ceiling	C. White distempered plaster matt	6·2	7·8	3·6
Floor.....	D. Wood block impregnated with white pipe clay.....	5·2	4·6	4·6

The artificial lighting is carried out by means of a single inverted arc lamp, burning pure carbons and suspended in the centre of the room, the distance from the arc to the ceiling being 2 ft. 6 in. The lamp absorbs, including all circuit losses, 500 watts, and the current consumption is therefore equivalent to 1·49 watts per sq. ft. of floor area.

The surface brightness of the various surfaces measured under the artificial light at 9:30 p.m. on June 9, 1911, is given in the following table.

Below the lamp and on the same vertical centre was suspended a white cardboard disc, 9 in. in diameter, below this a white wooden sphere 9¾ in. in diameter, and finally, and still on the same vertical centre line, was placed the white plaster statue seen in the illustration. The distance from the floor to the centre of the sphere was 7 ft. 9 in., and to the centre of the disc, which was fixed at an angle to the wall containing the windows of about 73 deg., 8 ft. 8 in.

Inverted Arc Light Tests.

Position.	Nature of surface.	Surface brightness (foot-candles).		
		Average.	Max.	Min.
Wall dado filling	A. Light brown glazed bricks	4·6	5·2	3·5
Wall above dado	B. Light greenish-grey distempered plaster matt	0·87	1·4	0·63
Frieze.....	C. White distempered plaster, matt	4·4	5·2	3·8
Ceiling	C. White distempered plaster matt.....	42·0	54·0	30·0
Floor.....	Wood blocks impregnated with white pipe clay	2·4	2·6	2·2

The photograph was taken at 10:30 p.m. by the light from the arc lamp only. The difference between the disc and the sphere is most marked, and the photograph, which was exposed to show the gradation of light upon the sphere, disc and statue, and is, in consequence, under-exposed as regards the walls, which therefore appear darker than they really are, conclusively demonstrates the fallacy of supposing the light and shade effect to be lacking, or the objects illuminated to be devoid of relief.

A comparison of the surface brightness of the three objects by daylight, and the light of the arc lamp respectively is instructive as indicating the remarkably close approximation of the inverted lamp light to the daylight, as regards the creation of light and shade effects.

The readings obtained were:—

Object.	Daylight.		Inverted Arc light.	
	Highest light.	Deepest shadow.	Highest light.	Deepest shadow.
Disc	3·2	3·2	3·5	3·5
Sphere	22·0	2·3	7·6	0·78
Statue	8·32	0·72	2·1	0·22

Measurement in foot-candles.

It is interesting to note that at the particular height and angle at which the disc happened to be suspended, the surface brightness (day 3·2, night 3·5 foot-candles) is almost identical by either daylight or artificial light, and that as regards the sphere and statue, whilst the daylight illumination is greater in intensity, the ratio between the highest light and the darkest shadow remains almost constant, being for the sphere, by daylight 9·5, and by artificial light 9·7, and for the statue by daylight 11·5, and by artificial light 9·5, results which, having regard to the fact that the particular installation of which the room shown forms a part, was not designed with a view to the obtaining of any precise ratio of light and shade, but merely the provision of a satisfactory and restful artificial substitute for daylight, may be regarded as a striking testimony to the value of this system of illumination. Close inquiries among users of similar lighting for purposes in which the obtaining of correct relief and contrast is essential, and of such diverse natures as wood-carving, sculpture, clay-modelling, wood and metal engraving, drawing from casts and from life, and the designing of tiles and textile fabrics, elicit the fact that whatever may be the case with indirect illumination by other illuminants, there is with indirect lighting by inverted arc lamps no difficulty in obtaining a light which is not only sufficiently colour-true to permit of painting in oil and water-colours being carried on by night, but is also a closer approximation to daylight (as regards the light and shade ratios obtainable by its use) than anything either yet available or likely, as far as can be seen, to be forthcoming for some very considerable time.

ELECTRICITY AND THE CORONATION.

There can be no doubt, in spite of the many grumblings to which it gives rise, that the Coronation is good for trade. This is directly due to a general desire on the part of people to see what there is to be seen, with the result that stands have to be erected for their accommodation and barriers for their protection. A feature, too, of all these celebrations is the illumination of the principal buildings and shops, a form of amusement which is directly advantageous to those engaged in electrical work.

It would be interesting to enquire when and for what reason what may be called building illumination was first started. Bonfires were, of course, used for signalling purposes, and it is not improbable that house illumination was undertaken on special occasions as an auxiliary to the rather meagre street lighting of the period. The flambeaux, which still exist at certain places, notably on the top of the Haymarket Theatre, and on several of the clubs, show what was done in the early days.

There is no doubt that the introduction of gas as an illuminant was a great incentive to the employment of decorative devices, such as crowns, stars, and mottoes, on occasions of national rejoicing, while with the more general use of electric light has come its employment for these purposes too, and the adaptation of the various devices to electrical working.

Compared with the Coronation of King Edward VII., electric lighting is being much more generally used; but apart from this there is very little novel to record. A number of places have contented themselves with erecting the Royal initials or monograms combined in some way with incandescent lamps, so that the device serves both as a day and night illumination. Others, more ambitious, are outlining the façade of their building with rows of lamps, sometimes of white alone and sometimes in red, white and blue, while in still other cases all the windows are outlined as well. In some very few cases, too, the illumination by means of incandescent lamps is combined with floral devices in such a way as to give a very pleasing effect at night. In fact, every effort has been made to make the decorations artistic, and the ease with which electric lighting may be combined with festoons, garlands, &c., has made the results in general quite successful.

Turning to particular cases, though it is perhaps rather invidious to distinguish where everything is so much the same, we may first mention the *Bank of England*. The scheme here is of interest, not only on account of its execution, but from the fact that this is the first time electricity has been used for the purpose. We understand that a sum of about £30 is being saved on the cost of lighting, extinguishing and re-lighting alone, and at the time of writing we have no doubt that the effect will be as splendid as it always has been, even though that flickering which is stated in some quarters to be so pleasing is absent. The main front of the Bank is lighted by three enormous monograms, and an equal-sized crown encircled by a wreath, these all being outlined by lamps. The façade of the building is picked out with rows of incandescent lamps, which run down the front of the columns and define the roof and sides, while on the front of the roof are a number of large glass pines supported on metal torch-shaped poles. Over 15,000 lamps are being used.

The *Royal Exchange*, where lamps are wound round the columns and lead across the portico, the *Mansion House* and the *Liverpool and Globe* office, as well as the adjacent buildings, are all artistically illuminated, and the open space in front of the Royal Exchange is sure to be the scene of a large crowd. Writing before the event we venture to say that it will form, in fact, one of the best illuminated areas.

Coming further west, one of the most novel devices is a large model of the "Olympic," which is fixed outside the office of the *White Star Line* in Cockspur-street. This model is lighted up from the inside, and shows every porthole aglow. Above it is an enormous white star, which is also electrically lighted.

The various clubs in *Pall Mall*, *St. James's-street* and *Piccadilly* have, as usual, taken this opportunity to go in for something extensive in the way of exterior illumination, though here again there is nothing very novel to be found. Initials and monograms are pretty general, and in many cases the buildings are outlined by rows of varied-coloured lights; in some cases the club's own monogram is also to be found. All the public buildings of the *London County Council* are decorated with cut-glass representations of the Royal crown and the City shield, and such symbols as "G. R.," while the Government offices content themselves with a cut crystal crown, which is placed over the main entrance, and serves both as a day and night decoration. Special mention may be made of the scheme adopted at the *Piccadilly Hotel*. The main pillars on the front of the building towards Piccadilly are coiled round with festoons of different coloured lights, while strings of lights hang between the pillars and a streamer of lights drops centrally from the festoon.

Attention may also be drawn to the scheme of lighting in *Piccadilly*. Festoons of imitation laurel are hung from the rows of Venetian masts on each side of the road, and these are combined with hanging incandescent lamps enclosed in globes of yellow uninflammable material. Every now and then these festoons are carried across the road in the same manner. These illuminations are fed from the mains of the Westminster Electricity Supply Corpn. through massive double-pole ironclad switches, which are fixed on the Venetian masts themselves, well out of the reach of the crowd. They are operated by a staff from the pavement, like the old-fashioned gas lamp.

Grosvenor Square-gardens are illuminated by incandescent lamps placed in Japanese lanterns. These are hung from the branches of the trees and are to be kept alight for 48 hours.

An unofficial scheme of illumination is to be found in *Cheapside* and *Cannon-street*, where the centrally hung flame arc lamps will, we fear, put many of the Coronation devices rather in the shade.

From the electrical engineering point of view it is gratifying to note that every possible precaution has been taken against fire risks. Permission to smoke will be very limited on the stands, and all care is to be taken to render both the electrical and gas lighted devices free from danger and tampering. Each circuit and sub-circuit in the case of electrical illuminations will be provided with double-pole fuses of suitable capacity, and the City Corporation recommend that the current in the sub-circuits should not exceed 10 amperes, while a similar restriction is imposed by the London County Council. Earthing of non-current carrying parts is recommended, while the temporary circuits should be connected direct to the main house switch to avoid overloading the house circuits.

A casual glance round the decorations at the time of writing shows that electricity is being much more used than on the previous occasion; and it will, therefore, be of interest to know how the increased demand is likely to affect the ordinary load on the stations. As regards the City, we understand that the only difference will be that the time of peak may be shifted on a little and lengthened out, but the winter demand is not likely to be greatly exceeded; for there will, of course, be no office or shop lighting, and thus a very considerable ordinary item will be removed.

In the West End matters are likely to be more serious, and every precaution is being taken to cope with a large demand. Unfortunately, some of the stations are pretty well loaded as it is, and benefits which would be conferred by linking up cannot be taken advantage of.

In conclusion, if a daylight view is anything to go by, the illuminations on the occasion of the Coronation of King George V. should be worth going a long way to see, and London for two nights, at any rate, should be turned into a "city of blazing light."

Accumulator Cars on Long Island Railway.—According to the "Electric Railway Journal," the Long Island Railroad has placed a single-truck storage-battery car in regular operation on its Bushwick branch to replace the steam trains. The car runs between Bushwick and Bushwick Junction, a distance of 3½ miles, and makes seven round trips.

CHEAPENING SERVICES FOR ELECTRICITY SUPPLY, WITH SPECIAL REFERENCE TO THREE-WIRE CONTINUOUS CURRENT WORK.

BY W. A. VIGNOLES.

Summary.—The cost of the different items that are comprised in a "service" is discussed in detail. Particulars are given of mains boxes that have been found suitable, the question of using one service for several houses is considered, and the author finally gives detailed costs of services at Grimsby.

The Effect of the Metal Filament Lamp.—The question of the cost of services is one that has been brought very forcibly to the notice of central-station engineers by the introduction of the metal filament lamp, as the small current consumed results in a reduction in the revenue from a given number of lamps and consequently per service. The situation is still further aggravated by the large increase in the number of small consumers; electric light is now so cheap that the smaller consumer is coming on to the mains very rapidly, and it is no uncommon thing for the writer to receive applications from small shops requiring only three or four lights.

The question is, how to reduce the cost of services so that these very small consumers may be supplied at a profit. In this connection prepayment meters have to be considered, as in many of these small shops the tenants change very frequently, and there may be a large percentage of bad debts unless the accounts are looked after very closely.

The Ideal Service.—At first sight the problem of a cheap service seems to be very simple, and it is possible, on paper, to lay services at a cost of 30s. each; but this figure is difficult to realise unless the distributors are laid under the footpaths close to the buildings and the meters fixed in the buildings near the street.

In practice many difficulties arise which prevent this ideal being attained except in a small proportion of cases; houses may stand back from the road, while there is frequently no convenient place for the meter near the street, or the consumer has some objection to the only possible position.

Under the Electric Lighting Acts the consumer can be asked to pay for all service cable laid on private property, but in the face of strong gas opposition this can very rarely be enforced. On the other hand, it is impossible to fix the meter exactly where every consumer would like to have it, as the cost would be prohibitive. To meet the consumer as fairly as possible, it is the rule at Grimsby to supply 40 ft. of service cable, outside the building, free of charge, and to fix the meter in a reasonable position in the building as close to the outside wall as possible. If the house stands further back from the road than 40 ft., or the consumer wants the meter fixed in some special position, the extra length of service cable is charged at cost.

Distributors on Each side of the Road.—Laying distributor cables on each side of the road reduces the cost of services, but increases the cost of mains, as two cables cost more than one of twice the section, while the length of ground to be opened and reinstated is doubled. In streets where there are detached houses standing in their own grounds, and consequently comparatively few houses per mile of street, it is probably more economical in many cases to lay the distributor on one side of the road only, in spite of the extra cost of long services across the road to half the houses. This extra cost is considerable, owing to the great expense of taking up the macadam or other road surface. In most streets two distributors will be more economical in the long run, although expensive at first.

Size of Service Cable.—If a service is only required for supplying electricity for lighting, the determining factor in deciding upon the size of cable will for most small houses be the mechanical strength. Metal filament lamps take such a small current at 230 volts that a cable merely large enough to carry the current may be too small to handle and lay underground in a satisfactory manner.

The question of cooking and heating by electricity has during the last two years forced itself upon the writer's attention, and owing to the large number of applications received for heaters and cookers, it has been decided to lay every service with a cable large enough to deal with the probable requirements in this direction even if no demand for heating is made when the service is first put in.

Two-way double-pole fuse boxes (four fuses) are fixed in houses where lighting and heating are both in use, so that the two circuits can be kept quite distinct with their own meters and main fuses. During the last 12 months 30 single-way boxes had to be changed for the two-way, and now, whenever a service is put into a house of a certain size, a double-way fuse box is put in as a matter of course. It will be obvious that these features increase the cost of the services, but the writer is confident that the right course to adopt is to endeavour to persuade everyone to use electricity for heating and cooking; it is not policy to cut the cost of every service to the lowest possible limit by putting in only such material as is absolutely necessary to deal with the first requirements of the consumer.

While, therefore, a very cheap service is required for cases of small shop lighting, the usual problem is to provide a service of sufficient capacity to deal with both lighting and heating for houses standing back fr the road where the length of cable required is frequently 40 ft. or 50 ft.

Cost of Service.—The cost of the ordinary service is made up of the following items, including labour in each case:—

1. Mains box.
2. Service cable.
3. Fuse box in house.
4. Meter.

Mains Box.

The cost of the mains box depends very largely on the type of distributor and service cable used. It is probably most expensive when arranged for triple-concentric distributors and concentric services; this is due to the necessity of cutting the outer and middle conductors of the T.C.C. and then making them continuous again. The most satisfactory way of doing this is to use cone or other mechanical grip connectors on the four ends of these conductors, coupling them together by means of links. A box of this character runs into money, but the cost may be minimised by arranging the box to take two services. In a fair proportion of cases the second service is used, and the cost of this second connection to the main is then very trifling. A box of this type is used by the writer and is shown in Fig. 1; it costs just under £1 with all fittings for distributor and two service cables.

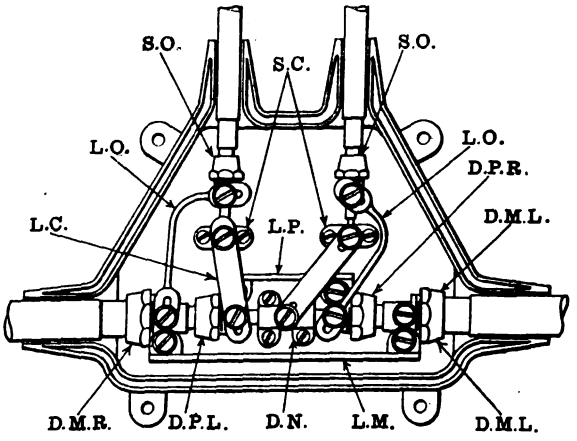

Fig. 1.—Double-Service Box for Triple-Concentric Cable.
Scale: 2 in. = 1 ft.

These boxes are made of cast iron, and were originally provided with screwed gun-metal glands on to which the lead of the cable was wiped; considerable trouble was experienced in keeping the glands watertight at the junction with the box, and after making careful experiments it was found to be quite possible to make a wiped joint between the lead of the cable and a boss or gland cast upon the *iron* box. This has been

Digitized by Google

found to be a great improvement, and has done away with the breakdowns due to faulty glands besides reducing the cost of the box. This type of box has to be made with a removable lid, to allow the second service to be introduced when necessary. This is a disadvantage, as it is very difficult to make such a joint perfectly watertight.

Box for Street Lighting Service.—The writer has recently had to run a large number of services for public incandescent lamps, and owing to the small revenue from each lamp the cost of each service had to be cut down to a minimum. For the lamps connected to triple-concentric distributors, the box shown at Fig. 2 was designed; all the lamps on this class of

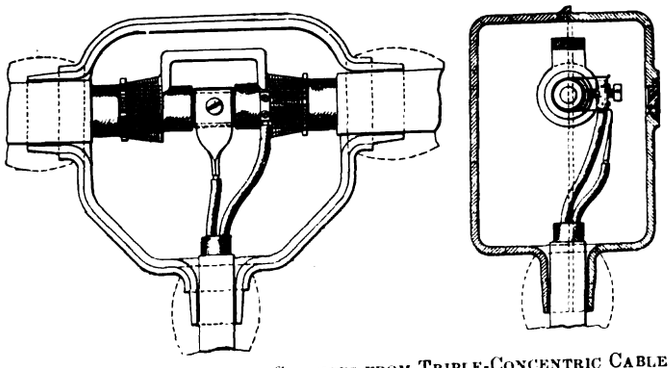

FIG. 2.—BOX FOR POSITIVE SERVICES FROM TRIPLE-CONCENTRIC CABLE

cable were connected to the positive side of the system (balance being obtained by connecting the lamps on three-core cable to the negative) so that it was necessary to cut the outer conductor only, the middle being simply bared to receive the connection; the inner conductor or core was, of course, not touched. The current required for each service is small, and sufficient contact is made by the copper strip nipped up on to the middle conductor with a Prescot fitting, without damaging the paper insulation underneath. The joints on to the outer fitting are made by binding the wires to the fitting and sweating; these joints have to carry the full current flowing along the main, so that they must be well made.

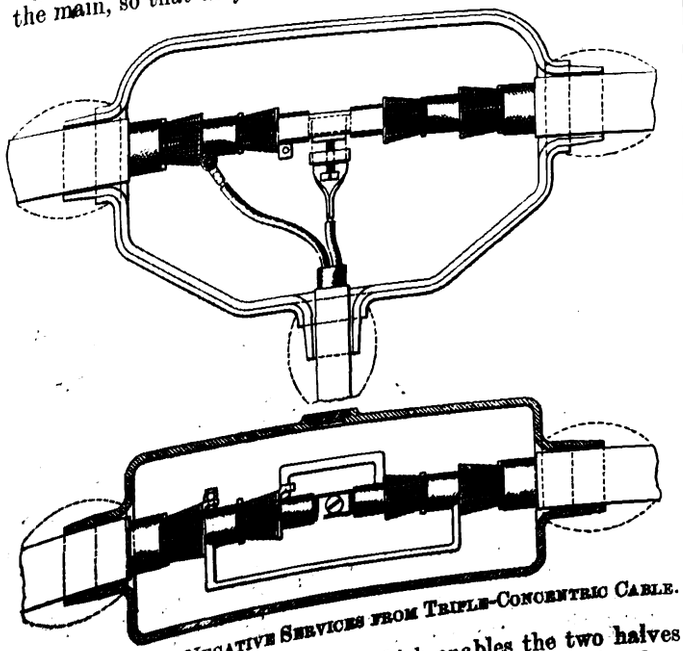

FIG. 3.—BOX FOR NEGATIVE SERVICES FROM TRIPLE-CONCENTRIC CABLE.

The box itself is of cast lead, which enables the two halves of the box to be sealed by soldering: this is much safer than any joint that can be made between the lid and the box where cast iron is used. Twin service cable is used connected direct to the fittings on the distributor, doing away with the fittings on the service cable. This box, with fittings, costs 5s. 6d.

It has been found by experiment that 30 to 50 amperes can be taken through this joint without heating, so that in future this box will be used for all services from the positive for not more than 20 or 30 amperes. (At Grimsby the core of the T.C.C. is negative and the outer is the middle wire.)

Lead Box for T.C.C. Work.—The box shown in Fig. 3 has been designed for negative services on triple concentric cable; the service cable would be twin and service connections would have to be capable of carrying 20 amperes at least. The cost of this box is about 6s. 6d.

Box for Three-Core Distributor.—With three-core distributors it is not necessary to cut any of the conductors; connections can be made by a Prescot form of fitting with a copper strip, as previously described. The box can therefore be considerably smaller than on triple-concentric cable, whilst the cost is also reduced by the reduction in the number of fittings. Fig. 4 shows the standard box of this type used with concentric service. The cost is 7s. 3d., while if the twin service is used, the cost is reduced to 5s. 6d. as no fittings are required for the ends of the service cable.

Twin Service Cable.—It is cheaper to use twin service cable in most cases, as, although it costs about 10 per cent. more than concentric, there is the saving in the mains box as mentioned above, and a further saving of about 9d. in the fittings in the fuse box, while labour in jointing is also less. The service would have to be a considerable length before the saving would be neutralised by the extra cost of cable, as this in the most usual cases would only be about 1d. per yard.

Fuse Boxes.—The writer is using a simple form of double-pole box for concentric services which can now be obtained at about 3s. 6d. The two-way double-pole box (four fuses) costs about twice the above. For twin cable the cost of the box is

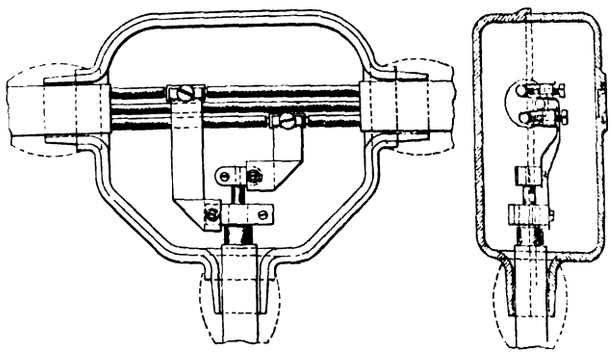

FIG. 4.—BOX FOR CONCENTRIC SERVICE FROM THREE-CORE.

reduced to 2s. 9d., as there are no fittings required. A smaller box suitable for 5 amperes and costing 2s. 6d. is used on the twin services for public lamps.

METERS.

For continuous current work the choice of a meter lies between:—

1. Electrolytic.
2. Commutator motor meter.
3. Mercury bath motor meter.

The electrolytic is the cheapest, but it suffers from the grave disadvantage that the reading is destroyed when the meter is re-set. Therefore, in case of a subsequent dispute, there is considerable difficulty in persuading the consumer that he has used the energy charged for.

The Reason Mfg. Co. have on the market a very neat combination of fuse box and electrolytic meter in one cast-iron case, which is very useful for small services, the meter reads to 100 units, and the whole arrangement is cheap and effective.

It is not necessary to discuss the merits and demerits of the various types of meter in a Paper on cheap services; each engineer must select the type he thinks most suited for his purpose, but the question of prepayment meters must be touched on, as this has to be considered when dealing with supply to small consumers.

Prepayment meters are useful in two ways, as a safeguard against bad debts and in simplifying the clerical work. The cost of a reliable prepayment meter is unfortunately somewhat

Digitized by Google

high, while the cost of emptying meters may be quite appreciable when they are first adopted, as the distance between one meter and the next will be considerable; this latter feature will, however, be of less importance as the number of meters in use increases.

The writer understands that in most towns where prepayment meters are in use they are set at a higher rate per unit than the ordinary price in the town. This is what is done by gas companies, but in their case free fittings are usually included, and it is difficult to show logically why the consumer using a prepayment meter should pay more for electricity than the ordinary consumer unless he receives some such special advantages. If he gets nothing more than the ordinary consumer but pays cash in advance, he should, if anything, receive a discount.

In Grimsby the ordinary charge is 3¾d. per unit with 1s. per quarter meter rent, while prepayment meters are set at 3d. For every shilling taken from the prepayment meters 2d. is returned to the consumer provided he is not in arrears on any account, so that the net price is about 4d. per unit without meter rent.

The electricity prepayment meter is a vastly different problem from the gas prepayment meter, owing to the small amount of power that can be used for working the mechanism, and it has taken a good many years' work on the part of the makers to produce a reliable type. The writer is using two different makes both of which are satisfactory, while there are several other types on the market that seem very promising but which he has not yet tried.

Cost of Complete Service.

The following figures show the average cost for the 296 services for street lighting which the writer has run in the last nine months:—

	s.	d.	£	s.	d.
Double-pole fuse-box in post	2	6			
Main-boxes and fittings	5	4			
Cable roughing, &c., average length of cable, 11½ ft.	7	4			
Total for materials			0	15	2
All labour except labour in reinstatements and inserting jointing	11	0			
Labour and materials			1	6	2
Reinstatement of roads and pavements carried out by borough surveyor's department, including reinstatement of ground after gas lamp was removed	5	9			
Total cost per service			£1	11	11

Labour and reinstatement are heavier than if the same number of services had been run to private houses, as the whole of the service is laid in the public streets under the pavements or roadway, and the cost of reinstatement after the removal of the gas lamps is also included. On the other hand, owing to the large number that had to be dealt with, it was possible to proceed in a very systematic manner, and this will have tended to keep down the cost of labour.

The cost of ordinary services varies very considerably, and depends on the special conditions of each job, but the writer's experience is that under normal conditions, using a fuse-box costing 4s. 9d. (which is the price paid until recently) and concentric service cable to three core distributor, the cost works out at about £1. 18s.

By using the cheaper fuse-box and twin service cable, the cost of the service, including meter on three-core distributors, would be reduced to £1. 14s. 3d., and using the box shown in Fig. 3 the cost of a negative service on T.C.C. distributors would be about 1s. more. This figure will represent the minimum, and not the average, cost of a number; the latter will be determined by the proportion of long services and services with two-way fuse-boxes.

Several Houses on One Service.—Eighteen months ago the writer considered very carefully the running of one service for a row of houses, as it was felt that unless something drastic of this sort were done, the cost per service would never be reduced to the limits desired. The idea was carried out in one row of semi-detached cottages by running a service into one house and looping from the fuse-box in this to the fuse-boxes in the other cottages. The result was satisfactory and considerably cheaper than separate services, working out at 30s. per cottage, notwithstanding that these stood 42 ft. back from the road and a long length of cable was required for the loop (underground) between the detached pairs of cottages.

The same idea was considered for terraces, but there are difficulties in the way of carrying it out. In the first place it is a question how many houses should be connected to one service in view of the demand arising for heating and cooking, while there is great difficulty in finding a suitable position for the looping cable between the houses.

After carefully reviewing the whole position it was decided to abandon the idea of putting a whole row on to one service, but to arrange one service wherever possible to serve a pair of houses. The houses in the terraces in Grimsby are all right and left handed, so that a meter fixed, say, under the stairs on the party wall is only separated by a few inches of brickwork from a meter in the corresponding position in the house next door. The arrangement, therefore, is to run a service into one house, and loop from the fuse-box through the wall to the box in the next house by a foot or two of twin cable.

During the last 12 months out of 213 services 30 have been "looped" in this way, the average cost of the "looped" service (without the original) working out at £1. 6s. 10d., the individual costs of these varying from £1. 14s. to about 14s., depending on the special conditions to be dealt with. No particular difficulties have been experienced with this method; where new houses are erected and services are put in before the houses are taken, the work is done in this manner as a matter of course, but in nearly all cases permission to loop from an existing box has been readily given when asked for.

The advantages of this system are:—

1. Reduced cost.
2. No opening or reinstatement of street.
3. Less time required to connect up, and therefore main disconnected for a shorter period.
4. Less inconvenience to the consumer; the work can all be done in two or three hours.

The only disadvantage is that the principal service has sometimes to be a little longer in order to make it suitable for looping.

The general effect of the efforts at reducing the average cost of services is well shown by the figures tabulated below. From these it will be seen that in four years the cost per service has been reduced about 25 per cent., and it is hoped to reduce the cost still further by using a larger proportion of looped services, and the boxes shown in Figs. 2 and 3.

Grimsby Electricity Department.

Mileage of Block Signals in the United States.—The Interstate Commerce Commission in the United States has issued a bulletin giving statistics of block signals in use on the steam and electric railways in the United States on January 1, 1911. Only those electric railways which are engaged in interstate commerce and are equipped with automatic absolute block signals are included in the tables. The total length of railways worked under the block system was 71,269 miles, an increase in one year of 5,511 miles. Of this amount 17,711 miles were equipped with automatic block signals. The increase in the mileage on which automatic block signals were used was 3,474 miles. Telephones were used for train dispatching on 41,717 miles of road, an increase of 17,373 miles during the year.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free,
Canada	28s. 3d.	14s. 6d.	7s. 6d.	payable
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	in advance.

New volumes of "THE ELECTRICIAN" *commence in April and October.*

(This charge includes all the numerous Supplements.)

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

'THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the 1911 Edition sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription, 5s., post free.

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Now Ready.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d. *Now Ready.*

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms only, bound strong cloth. Price 5s. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Cerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY. AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. [Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. C. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d. [Price 10s. 6d. nett.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.: post free, 2s. 3d.

ACCIDENTS IN FACTORIES AND WORKSHOPS.

A certain loss of life and limb seems almost the inevitable penalty of industrial work in factories, and although employers may do everything in their power to protect their workmen, the number of accidents must still largely depend on the care exercised by employees and the extent to which certain rules are observed. This is particularly the case where electrical machinery and apparatus are concerned. The accident roll in this country is heavy, but it compares very favourably with that in other countries, due largely to the greater attention that is here paid to render apparatus used by both skilled and unskilled labour "fool-proof," that is to say, in protecting the workman as far as possible from the penalties of negligence or wilful disregard of regulations. The recently issued annual report of Dr. B. A. WHITELEGGE, H.M. Chief Inspector of Factories, shows that 129,550 accidents in factories and workshops were reported last year. When the accident roll in the mining industry is added to this, the total appears stupendous; but, fortunately, only a very small percentage of the accidents terminate fatally. The number of accidents in factories mentioned above includes only 1,080 in which fatal results followed, both figures showing an increase over those of the two previous years, largely, if not wholly, due to improved trade and more employment. It is satisfactory, moreover, to notice that whilst the total number of accidents in 1910 is 4 per cent. greater than in 1907, the number of fatalities is 9 per cent. less. In view of the present tendency to make more and more use of machinery, no striking reduction is to be looked for in the total number of accidents reported.

Digitized by Google

any rate in the near future, but greater attention to fencing round machinery and to improvements in design of apparatus should reduce the proportion of accidents to the number of persons employed. On the other hand, the tendency of recent legislation to place greater responsibility on the employer may possibly have a counteracting effect.

If we turn our attention to electrical accidents, the record set out in the sectional report of Mr. G. Scott Ram, H.M. Electrical Inspector of Factories, is in one respect by no means unsatisfactory. In fact, in view of the enormous increase in the use of electrical apparatus during the last four years, the figures for 1910 compare, we think, very favourably with those for 1907. Thus, whilst last year 276 electrical accidents occurred in factories other than electrical stations, the number in 1907 was 258, whilst the number of fatal accidents has decreased from eight to five during the same period. A decrease has also taken place in the number of electrical accidents in generating stations and sub-stations. Improvements in the design of apparatus are undoubtedly largely responsible for the smaller percentage of accidents, although, of course, it is practically impossible to do more than estimate to what extent there is greater freedom from accidents, since the increasing use of electric motive power in factories can only be roughly ascertained. In this connection reference may well be made to our annual statistics giving the horse-power of motors connected to public supply mains. Much credit for the improved position must also be given to the efforts of the Home Office to ensure that electrical installations in factories shall attain at least to a certain standard of safety. The Regulations issued by the Home Office in 1909 and the subsequent Memorandum of Mr. Ram have done much to bring about an improved state of affairs; but in view of the fact that many owners of factories understand little or nothing about electrical apparatus, so that they are unable to say in what respect their plant fails to comply with the Regulations, progress must naturally be slow. In fact, a large proportion of the occupiers await instructions from the Inspector before taking any steps whatever to comply with the Regulations. Notwithstanding the delay thereby introduced, much good work has so far been done in removing obvious defects, such as bare conductors, unprotected fuses, &c. The difficulty involved, however, in bringing about the alterations desired is obvious from the fact that even electrical engineers themselves have not in many cases realised all that is implied in the Regulations, whilst some actually even admit not having seen them. Moreover, it is not only old installations that are involved, since some recent work does not comply with the requirements.

Although, as shown above, the record of electrical accidents is in one respect satisfactory, closer investigation shows that a large proportion of the accidents can be classed as preventable. Thus of 276 accidents in factories other than generating stations, 20 resulted from the use of flexible wires the covering of which was worn out or damaged, whilst 48 accidents occurred with switches—in nearly all cases due to bad design—and 24 with unsuitable plug connectors. Improvements in design take some time to bring about, but manufacturers are now paying much more attention to the various features to be guarded against, and in this connection Mr. Ram has rendered valuable assistance by the suggestions in this and previous reports, many of such suggestions having been acted upon. Moreover, the list of accidents might easily be reduced by nearly 20 per cent. if steps were taken to prevent unnecessary work being done on "live" switchboards, &c. Such work accounted for 51 accidents last year, skilled persons being concerned in two-thirds of the cases. As Mr. Ram points out, there is rarely any reason in the case of factories why any such work as may be necessary should not be carried out when the installation is "dead."

One of the most striking features of the fatal electrical accidents last year is that nearly half of them occurred on circuits at pressures which are usually considered not particularly dangerous. Thus of the nine fatalities, it is believed that the shock received in four cases was at from 200 to 250 volts. We think that particular attention should be called to this fact, since "low-pressure" circuits are not always treated with the respect that is their due under certain conditions. It is also interesting to notice that although most accidents, generally burns, occur with continuous current, alternating current is responsible for eight of the nine fatalities.

NOTES ON FUEL ECONOMY.

BY C. E. C. SHAWFIELD.

Summary.—The author emphasises the importance of calculating what the efficiency of any given station should be and then carrying out tests to ensure the efficiency approaching this figure. Notes are given on the working of engine-room plant, more particularly steam turbines, and the working of the boiler house. In conclusion, the author recommends a bonus scheme for the boiler-house staff, based on the evaporation of water per pound of fuel.

The power-house equipment of every central station may be divided broadly under two headings—viz., Engine Room and Boiler House. In the latter the object to be attained is the production of steam with the minimum expenditure of heat units, and in the former the production of electrical energy with the minimum weight of steam. Unfortunately, however, the path from the coal pile to the 'bus bars is of such a devious character and offers so many avenues of escape that comparatively few of the heat units contained in the fuel arrive at their destination in a saleable form. It must be admitted at the outset that the ideal efficiency of 100 per cent. is somewhat beyond the limits of practical endeavour; but, nevertheless, it is probable that there are but few power stations where the actual efficiency attained is within an appreciable percentage of the best result which is commercially possible.

It is rather instructive to determine by a few simple calculations what should be the best all-round efficiency of any central station as expressed in pounds of fuel consumed per unit generated, and it will frequently be found that the discrepancy between this calculated figure and the average daily working result is a good deal larger than it ought to be.

The following data are usually available in any central station, and are practically all that are required to form the basis for interesting and useful investigations:—

1. The test-bed efficiency of each generating set in the station at half, three-quarters and full load, expressed in pounds of steam per kilowatt-hour. This figure must include all steam used for auxiliaries.

2. The load curve of an average day at different seasons of the year.

3. The efficiency of each boiler, or class of boiler, installed in the boiler house, expressed in pounds of water evaporated from "feed" to steam per pound of fuel fired. These boiler

Digitized by Google

efficiencies should represent the result obtained under the best conditions: that is, with the boiler clean and in good condition, all brickwork and settings sound and air tight, and assuming careful firing and steady load.

From these data there may be deduced certain standards of efficiency which represent the best results that it is possible to obtain from the plant installed in the engine room and boiler house respectively.

In the engine room the result should be expressed as pounds of steam consumed per kilowatt-hour generated, and in the case of the boiler house as pounds of water evaporated from feed to steam per pound of fuel consumed. These two results, of course, suggest a third—viz., the fuel consumption per unit generated. The figures obtained in this manner will, of course, vary very greatly in different stations under different conditions of generating plant, load factor and output; but, nevertheless, it will be found that practically every station has a certain "best possible performance" which may be determined from data readily obtainable, with a reasonable degree of accuracy, and these standards once determined are of considerable assistance in tracing and eliminating many sources of loss.

Let it be assumed that the calculations previously referred to have been made, and that certain values have been arrived at which may be, for a fairly average case, as follows:—

1. *Engine Room.*—A mean consumption of 24 lb. of steam per kilowatt-hour throughout the 24 hours under the average conditions of steam pressure, steam temperature, vacuum and load.

2. *Boiler House.*—A mean evaporation of 8 lb. of water from feed to steam per pound of fuel consumed.

3. *Deduced from* 1 *and* 2.—An average consumption of 3 lb. of coal per kilowatt-hour generated through the 24 hours.

In making the above calculations it will be assumed that the supplies of fuel are fairly uniform in their calorific value and in the percentage of moisture and ash contained.

It now becomes necessary to conduct a series of further investigations to ascertain to what extent the actual results obtained compare with the calculated standards, and it is here that the real difficulties are encountered. In the great majority of power stations the consumption of fuel is measured daily or weekly (usually the latter), and compared with the corresponding output of units at the 'bus bars, and a figure is thus obtained which gives the fuel consumption per kilowatt-hour generated. Unfortunately, however, there are but few cases in which it is known with any degree of accuracy what is the mean steam consumption per unit generated, or the average evaporation of water per pound of fuel burnt, and it is precisely these records which are the most valuable when the question of fuel economy is under consideration.

The Engine Room.

In the case of those stations which run under non-condensing conditions, or where the generating sets exhaust into condensers of the jet or ejector type, there are certain obvious difficulties in obtaining anything like a continuous record either of the steam consumption of individual sets or of the total steam consumption of the station. Nevertheless, there are two methods in which this may be done with a fair approximation to accuracy. One method is the insertion of steam meters of the disc type in the branch steam pipe to each generating set; the other is by passing the whole of the feed water to the boilers through some form of meter or recorder which gives a continuous diagram on a chart.

If the former method—that is the use of steam meters—is adopted, it is fairly easy to obtain a continuous record of the performances of the individual generating sets; but some time and trouble is necessary to combine the individual records in order to ascertain the performances of the engine-room plant as a whole, and the risk of error is considerably increased. Since, however, the mean performance of the engine-room plant as a whole is of more importance than the individual performance of any set, better results could probably be obtained from continuous measurements of feed water to the boilers. If this method be adopted it is necessary to see that a constant level is maintained in the suction tank or hot well which supplies the feed pumps, and also that the water in the boilers is maintained accurately at a constant level. If these precautions are adopted the feed input to the boilers will correspond within certain definite limits to the steam output to the engine stop valves, the inevitable discrepancy being accounted for by loss of water through the boiler blow-offs, through condensation in the steam range, and also by loss of steam through the boiler safety valves.

If, as is frequently the case, the whole of the generating sets exhaust into surface condensers, the obtaining of continuous records, either of individual sets or of the total consumption of the engine-room plant, becomes a very simple matter indeed, and the installation of recorders of the "V" or square notch type will prove to be a very sound investment.

If possible, arrangements should be made for separate measurements to be taken of the steam which has been usefully employed (that is, which has passed through the prime movers and returned through the condensers), and of the steam which is wasted by condensation in the steam range, separators, &c., and which is returned by the traps. The make-up water required by the boilers may also be included under this latter heading.

If it has been possible to obtain a continuous record in the form of a diagram of the steam consumption of the generating sets on any particular day, it is a simple matter to obtain by

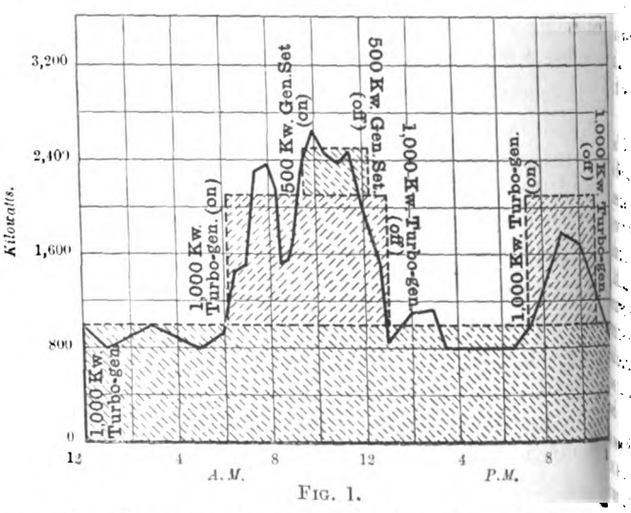

Fig. 1.

integration the average consumption throughout the 24 hours and also the actual consumption per hour at any period of the day. The average consumption throughout the 24 hours can be calculated and some of the causes of any excess consumption may be ascertained by a careful inspection of the diagram itself. For example, if at any particular hour of the day the actual recorded consumption of steam per kilowatt-hour generated is considerably in excess of the calculated standard it may be assumed that the set or sets in service at that time are consuming very much more steam than they should be at that particular load, or that the relation of generating sets to load—that is, plant load factor—is not the best that can be obtained. If the former supposition should prove to be correct then the obvious remedy is to overhaul the generating sets and their auxiliaries. If, however, the latter assumption is found to be true, then the overhaul is equally necessary in the case of the shift engineers and the running staff.

The plant load factor has an extremely important bearing upon the question of fuel economy, and a difference of from 5 to 10 per cent. in fuel consumption may readily be occasioned by good or bad arrangement of the apportionment of plant load. A useful method of checking the abilities of the running staff in this direction is to have plotted on the daily load curve a diagrammatic representation of the amount of engine-room plant in service each hour of the day. An example of such a combined load curve and diagram is shown in Fig. 1.

Digitized by Google

In cases where any excessive steam consumption is traced to any particular generating set or sets, indicator diagrams should be taken at various loads and then compared with the original diagrams taken by the makers at the official test. An inspection of these will frequently indicate the cause of the trouble. In reciprocating engines of the high-speed vertical type, the excess steam consumption is often due to wear at the piston valves and rings, or to badly fitting or defective high-pressure piston rings. Inaccurate valve setting is sometimes another source of trouble, although the existence of defects of this description should be apparent on an inspection of the indicator diagram.

In the case of steam turbines the following principal causes of high steam consumption may be looked for :—

1. *Blade Stripping.*—Fortunately at the present day cases of blade stripping appear to be less frequent than they were a few years ago, due, no doubt, to the fact that the operation of turbines is somewhat better understood than was formerly the case, and to experience having shown what precautions are necessary to prevent this annoying class of breakdown. Nevertheless, it is quite possible at any time that a partial strip may occur at the high-pressure end of the turbine without giving any external evidence, and several cases have occurred where it was only when the turbine had been opened up that the discovery was made that a more or less complete strip had occurred on several rows of the high-pressure blading.

In the case of turbines of the reaction type, which are more subject to trouble of this description, it will usually be found that the stripping of two or three rows of the high-pressure blades results in a lower steam chest pressure throughout the whole range of load, and this is an indication which should be looked for should it be suspected that a partial strip has occurred.

2. *Excessive Radial Clearance owing to the wearing away of Blade Tips or Blade Shrouding.*—This is a defect which sometimes arises from unequal heating of the rotor when starting up, resulting in the rotor becoming temporarily distorted and bringing the blade shrouding or blade tips in contact with the shaft and casing. Although very little actual damage may be occasioned by an occurrence of this kind, yet sufficient metal may be removed from the shrouding or blade tips to increase appreciably the radial clearance, with the natural consequence that the steam losses through leakage past the blading are considerably increased.

3. *Steam Leakage round the Dummy Pistons.*—This is probably one of the most usual sources of loss in steam turbines after they have been running for a year or two, and the presence of this defect, as a rule, can only be clearly established by careful measurement of the actual clearances. Fortunately, it is usually easily remedied by readjustment.

4. *The Partial Choking up of Rows of Blades by the Deposition of Mud carried over by the Steam.*—This condition of things is apparently caused by the carrying over of mineral matter which is held in suspension by the steam, and is gradually deposited on the low-pressure blading. As a rule this deposition does not occur until after the steam has expanded down to atmospheric pressure or below, but once it has commenced the low-pressure blading of the rotor and the casing becomes covered with a fairly hard chocolate coloured mud, until sometimes entire sections of blading are almost completely choked up. The first symptoms of this species of defect are a falling off in the rated capacity of the turbine, together with an appreciable increase in the steam consumption, and the only remedy is a somewhat tedious process of cleaning each individual blade by means of scrapers and compressed air blast. As a means of preventing trouble of this description, care should be taken to see that the concentration of mineral matter in the water contents of the boilers is kept at a reasonably low figure.

It is not very often that excessive steam consumption is due to the auxiliary appliances in the case of reciprocating engines, this type of prime mover is much less affected by variations in vacuum than is the case with the steam turbine; and, indeed, it is very doubtful whether, in the interests of economy, it is advisable to attempt to obtain a higher vacuum than 24 in. to 25 in. in the case of reciprocating engines. Beyond this point very little decrease of steam consumption is effected, whilst any little saving there might be is more than counterbalanced by the lower temperature of the water of condensation, and by the additional power absorbed by the auxiliaries.

So far as steam turbines are concerned, the circumstances are entirely different; here the reduction in steam consumption as the vacuum is improved is very marked indeed, being approximately 5 per cent. for each inch of mercury above 26 in. The condensing plant of a turbo-generator is, therefore, a very important item, and not infrequently the increased steam consumption in the case of turbo-generators may be traced to a fall of vacuum in the condensers, which has not been revealed by the usual Bourdon gauge. The best form of vacuum gauge is undoubtedly the differential type, as illustrated in Fig. 2. These instruments are perfectly reliable, and have the advantage that they always record the true absolute pressure at the condenser, irrespective of barometric variations. Moreover, they are easily made and are not liable to derangement.

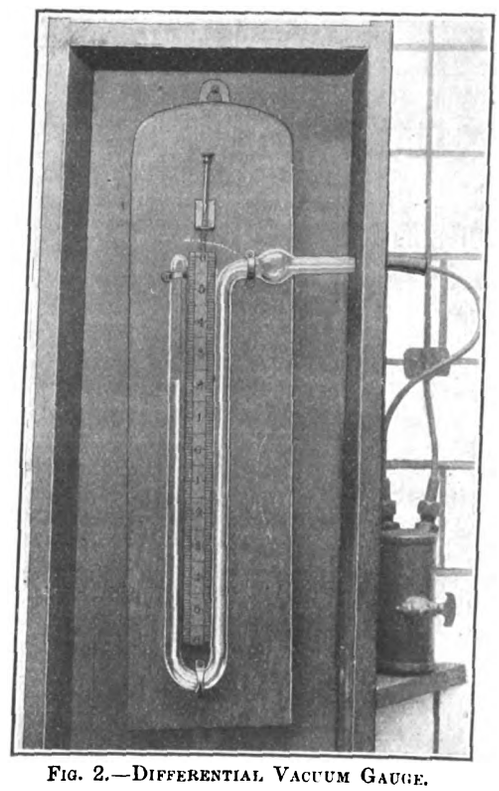

FIG. 2.—DIFFERENTIAL VACUUM GAUGE.

If the vacuum in any case is found to be considerably below standard, the causes may be looked for in the following directions, viz. :—

1. Air leakage.
2. Air-pump defects.
3. Insufficient supply or too high temperature of circulating water.
4. Choking of condenser tubes with scale or other foreign matter.

In the case of the first three causes the remedy is obvious.

In the fourth case—viz., the presence of scale—an effective method of dealing with it is to circulate dilute hydrochloric acid periodically through the water space of the condenser. When doing this it is necessary to see that both inlet and outlet branches are blanked off or otherwise closed, to prevent the acid reaching the circulating pump on the inlet side or escaping prematurely at the outlet. If the dilute acid is circulated through the tubes by means of a small pump for two or three hours it will be found that practically the whole of the scale is removed and the tubes are left clean and bright.

A careful investigation of the engine-room plant conducted generally on these lines will go a long way towards bringing the

Digitized by Google

actual performance of the station, so far as the engine room is concerned, to a point within reasonable proximity to the standard which has been arrived at by calculation. It now remains to be seen what improvement can be effected on similar lines as regard the boiler-house equipment.

The Boiler House.

The first step to be taken is the measurement of the total weight of feed water delivered by the feed pumps, and if possible this measurement should be made in the form of a continuous record, so that it may be compared on a time basis with the corresponding record of steam used in the engine room. The difference between the total quantity of water put into the boilers and afterwards recovered from the condensers in any given period will form the basis for calculating the total number of heat units wasted in blowing down boilers, by condensation in the steam pipes, &c., and by the loss of steam through the boiler safety valves. Furthermore, if the measurements be in the form of a continuous record for any period, not only will the total amount of this loss be capable of calculation, but, what is of equal if not greater importance, the time of day at which the greatest amount of loss occurs will also be available.

Armed with this latter information, the task of reducing those losses is considerably simplified. It will sometimes be found that the losses through condensation in the steam pipes, &c., are greater at times of light load than full load, in spite of the fact that under light-load conditions the total weight of steam dealt with is very much less. This may be due to the fact that at light-load periods the rate of flow of steam through the pipes is greatly decreased and the degree of superheat is probably considerably lower.

As a method of reducing these condensation losses, careful attention must be paid to the condition of the lagging, and particularly to the covering of the steam pipe flanges and valve bodies. Moreover, the application of the bulb of a thermometer to the exterior surfaces of the lagging will in many cases reveal surprising differences of temperature, and will lead to the discovery of defects which might otherwise pass unnoticed.

The number of boilers in use at light load should be reduced to the minimum, the object being to carry the load on one or more boilers working at as nearly as possible their most efficient rate of evaporation, the remainder of the boilers being shut off the range and carefully banked.

The actual hourly evaporation of the boilers, as determined generally from the measurements of boiler feed and of engine-room steam consumption, should be plotted in the form of a curve on a scale diagram showing the number and capacity of the boilers actually under steam for each hour in the day. The capacity of each boiler is to be taken at that rate of evaporation at which it gives the highest efficiency. This curve will indicate the boiler load factor at any hour in the day, and it can readily be determined whether the boiler-house staff are working the plant under the most suitable conditions or whether fuel is being wasted through several boilers being operated at very inefficient rates for a number of hours in the day.

Unfortunately, it is very difficult to obtain anything like a continuous record of the total coal consumption over any given period, and in the great majority of cases the only method by which it can be arrived at is the somewhat expensive and laborious one of hand firing every boiler and measuring the total quantity of fuel fed thereto hourly. Nevertheless, even if this method be adopted, the results obtained will be found worth the trouble involved; and if plotted on a chart containing also the load and water consumption curves, the information which may be deduced therefrom will prove both interesting and valuable. In the majority of cases, however, the only coal measurements available will be the total quantity consumed daily or weekly, and this figure divided into the total water evaporated for the same period will give the mean evaporation from feed to steam per pound of fuel. It is to be feared that the figure thus obtained in everyday practice will be very much below the calculated standard, which, after all, represents a standard of boiler efficiency which is only likely to be obtained in a station possessing an abnormally high plant load factor.

Among the most potent sources of loss in the boiler house generally is the presence of scale or mud on the water surfaces of the boilers, and of soot or other incrustation upon the fire surfaces. In fact, it may be said that the highest possible degree of cleanliness of the inside and outside of the boiler is one of the primary requisites of efficiency.

It seems hardly necessary to refer to the wisdom of careful inspection of the brickwork of the boiler settings and of the flues to ensure that air leakage is reduced to a minimum, and that the thickness of the walls is sufficient to prevent undue loss by radiation. In this connection it should be noted that fireclay should not be used in boiler settings, or brickwork generally, unless the temperature is sufficiently high to flux it, otherwise in a short space of time it crumbles away, and loose, shaky brickwork, with all its attendant evils, is the result. Bricks if laid in cement, and if ample time is allowed for the latter to set naturally, will stand very much greater temperatures than is commonly supposed without the slightest deterioration.

If it be found that the boilers generally, the economisers and flues are in a good condition, it may be assumed that improved efficiency may be looked for in an alteration in the method of operation. In this direction improvement will usually be found obtainable only by constant experiments by a careful and frequent use of a CO_2 recorder of the Orsa type, and last, but by no means least, by giving the boiler house staff a practical interest in obtaining improved results.

If, for example, it has been determined that the best possible performance so far as the boiler house is concerned is the evaporation of 8 lb. of water from feed to steam per pound of fuel consumed, and that the average performance under normal working conditions is only 6½ lb., then a bonus scheme might be initiated somewhat on the following basis:—

The bonus to take the form of a percentage increase on wages according to the amount of steam generated per pound of fuel consumed above a certain minimum—that is, no bonus to be paid unless an evaporation exceeding, say, 6·6 lb. of water per pound of coal is obtained. For each one-tenth of a pound above this a bonus to be paid to the boiler-house staff as follows:—

Evaporation.	Bonus.
6·6 lb. of water per lb. of coal	Nil
6·7 lb. " "	2½%
6·8 lb. " "	5%
6·9 lb. " "	7½%
7·0 lb. " "	10%
7·1 lb. " "	12½%
7·2 lb. " "	15%
7·3 lb. " "	17½%
7·4 lb. " "	20%
7·5 lb. " "	22½%

These figures are, of course, only for the purpose of illustration, and the scale of bonus must necessarily depend upon purely local conditions, such as rate of wages, price of fuel, and also upon what is the maximum degree of improvement likely to be obtained.

The necessary calculations should be got out every week in a tabular form, and the result posted up in the boiler house, the actual bonus may be paid monthly or quarterly. In making these calculations allowance must be made for the water which is lost by periodical blowing down of the boilers, and it is advisable to arrange that each boiler is blown down at certain stated intervals and to a certain definite amount in the gauge glass, the operation being performed under the supervision of the boiler-house superintendent or the charge engineer. To illustrate this method of calculation, a typical weekly scheme of results is given in the following Table.

It may be, and has been, argued that a bonus scheme of this character is immoral, inasmuch as it attempts to secure by bribery that efficient service which should be freely rendered in return for the normal wages. This may or may not be true, but it is certain that, pending the arrival of the millennium, payment by results will always produce more efficient work than any other method of remuneration.

Digitized by Google

In conclusion, the writer desires to emphasise the paramount importance of keeping continuous records of boiler-house and engine-room performances, as without such records it is very difficult, if not impossible, to discover and eliminate the many sources of loss, and to maintain a reasonably high standard of efficiency.

CORRESPONDENCE.

THE TELEPHONE TRANSFER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The views of Mr. Hirst on this subject, so fully expounded at the meeting of a manufacturing company and so widely circulated in the Press, deserve some comment. It may be perhaps considered cynical to suggest that those views are somewhat coloured by a lively sense of orders to come; but I am impelled to that suggestion both because Mr. Hirst's published opinions are in direct opposition to those of almost every member of the electrical industry having knowledge of the subject, and of most of the technical, financial and lay Press, and because the Post Office looks like being the only future customer in this country for the Company for which Mr. Hirst was speaking.

As a business man, Mr. Hirst should find some difficulty in advocating so ardently the transfer of a business which under commercial management is operated at 58 per cent. of the gross receipts to a Department which operates the same business at over 74 per cent. of the gross receipts. The difference represents over 3 per cent. on the capital employed, which much more than offsets the lower rate of interest at which Government can raise capital as compared with a company or a Telephone Authority.

The telephone service is at present very little developed in this country, a state of affairs which *is*—Mr. Hirst to the contrary notwithstanding—very largely the fault of the Post Office, as the Post Office telephone policy has been obstructive from the very beginning.

To accelerate the development of the telephone, which has been artificially restricted for years past, requires large expenditure of capital. Mr. Faithful Begg, in a recent Paper before the London Chamber of Commerce, put the capital required for the next 10 years to develop the telephone adequately in the United Kingdom at £116,000,000. Is it likely that the Post Office, which earns a bare 3 per cent. on its telephone business, will be able to induce the Treasury or Parliament to invest any such sum in a Government telephone monopoly? It may be argued that when the National Company's business is taken over, the telephone profits of the Post Office will be greatly increased. So they will—for a year or two. But in time the same causes, relentless as the tides, which have turned the telegraphs into a losing business will wipe out the telephone profits: it is only a matter of time, if the telephone becomes a Government monopoly, when the Postmaster-General of the day will tell a thin and bored House that the telephones, like the telegraphs, are "past praying for."

As to pushing the telephone business, if that is not done by a trained business department much confusion would result. One powerful argument for a Telephone Authority is that under such management the very important question of business relations with the public would be adequately dealt with.—I am, &c.,

Westminster, June 17. HERBERT LAWS WEBB.

THE IMPERIAL CONFERENCE AND TELEGRAPHY.

Reduction of Cable Rates.

At the meeting of the Imperial Conference on Thursday last week Sir JOSEPH WARD presented a motion dealing with the subject of inter-commercial communication. He moved:—

> "That in view of the social and commercial advantages which would result from increased facilities for inter-communication between her Dependencies and Great Britain, it is desirable that all possible means be taken to secure a reduction in cable rates throughout the Empire."

Sir Joseph urged that the great question of cheapening cable rates between the Mother Country and her Dominions and dependencies had engaged attention for some years past and much had been actually accomplished, but the cheapening of rates had not gone nearly far enough. The cheapening of postal service had shown that not only was more use made of the reduced service, but the working was more profitable. The high cable rates were, he contended, injurious from the public point of view, and restricted their use, and he hoped action might be set on foot by the Conference to bring about an improvement.

The Postmaster-General (the Right. Hon. H. L. SAMUEL) said the Home Government sympathised with and supported this view, as, as Sir Joseph Ward had said, some progress had been made. Since the last Imperial Conference the Press rates to Australia had been reduced from 1s. to 9d. Steps were being taken by the United Kingdom to bring about the cheapening of rates in several directions. They had secured the consent of the principal cable companies to a reduction of 50 per cent. in the rates for cablegrams in plain language which might be deferred for a period not exceeding 24 hours, and they hoped that, with the approval of foreign administrations interested, the new rates might be shortly introduced. Secondly, negotiations were pending with a view to securing a further reduction of Press rates. Thirdly, the Government intended to adopt the policy that in all new landing licences there should be a clause giving effective Government control over rates, with due security to the companies against abuse of that power, in the form of an appeal to the Railway and Canal Commission. Fourthly, the development of the wireless telegraph system must have some effect on cable rates.

Sir WILFRID LAURIER pointed out the trouble was with the Atlantic cables. There was an impression in Canada, almost amounting to a conviction, that a combination existed in connection with the old cables, and the remedy suggested by the Postmaster-General was, he thought, a sound one for dealing with that combination, if it existed. In Canada they were acting on more or less the same lines.

The Hon. A. FISHER said Australia and New Zealand were dependent entirely on the cables for information as to public affairs, and he desired to know whether it would be feasible to grant a low rate, so far as the Pacific cable was concerned, for news cabled from Australia to Montreal, whence such news might be posted?

The Hon. G. F. PEARCE said the end they had in view was the development of the transmission of news between all parts of the Empire. Rates had been brought down, not by the voluntary action of the cable companies, but by the threat to lay the Pacific cable. The policy of the various Colonial Governments in bringing about reductions of rates had been to achieve that result, even at a loss. Such a policy could not be followed by the Railway and Canal Commission, as that body would decide the rates on such a basis as to leave a profit to the operating companies; therefore, the proposal would not secure the full result desired although it might be an improvement. Would the Postmaster-General give him some information regarding the refusal of the Treasury to sanction the construction of a new cable, which would mean an increased revenue to the Pacific Cable Board of £14,000 between New Zealand and Australia, the ground of refusal being that it would interfere with developments in connection with wireless telegraphy.

Sir DE V. GRAAFF said it would be a matter of great gratification to South Africa if the efforts outlined by Mr. Samuel were brought to a successful issue. A 50 per cent. reduction was a substantial concession, and the large number of people who did not use code would find their cabling facilitated and would benefit at once. He was glad to hear also that a reduction in the Press rates was contemplated. The Union of South Africa subsidised the Eastern & South African Telegraph Co., as in each year the company's revenue did not reach a certain sum the Government paid a certain amount, and had been doing so for some years past. The reduction outlined by the Postmaster-General would mean, of course, the continuation of that subsidy, but, in view of the advantages to be derived, the Union Government did not object. They were in favour of the reduction of cable rates throughout the world, and he supported the resolution.

Sir E. MORRIS also supported the motion.

Mr. SAMUEL said he would represent to the Chancellor of the Exchequer the strong desire felt by Australia and New Zealand that the Pacific Cable Board should be authorised, so far as the United Kingdom's consent was concerned, to proceed with the work to which Mr. Pearce had referred.

Digitized by Google

Mr. ASQUITH promised further consideration of the matter, and the resolution was then agreed to.

Nationalisation of the Atlantic Cable.

The Hon. G. F. M. PEARCE then moved :—

"That this Conference strongly recommends the nationalisation of the Atlantic cable in order to cheapen and render more effective telegraphic communication between Great Britain, Canada, Australia and New Zealand, by thus acquiring complete control of all the telegraphic and cable lines along the 'All-Red Route.'"

Mr. Pearce said that in Australia they believed the only way any beneficial result could be secured was by nationalisation. Any proposal for an "All-Red" telegraph route involved laying a cable across the Atlantic and erecting a land line across Canada. The estimated cost of such a scheme would be £480,000 from Killala to Newfoundland with a connection to Nova Scotia and £120,000 for the land line across Canada. The estimated annual expense of working and maintaining the cable was £21,500 and of the land line £32,500, against which would be set certain existing expenses which would be incurred no longer (£22,000), leaving a net annual expenditure of £32,000. It was further estimated that a revenue of £36,000 would come in at once, in addition to new business which would probably accrue. He believed the scheme for an "All-Red" route was perfectly feasible, and was not likely to require special financial assistance from the Governments. Every attempt to obtain improvement in the existing service, either for business or Press purposes, was blocked by the Atlantic companies. The Pacific Cable Board carried Press messages over 10,000 miles of sea and land for 3d. per word, whilst the privately-owned cable companies charged 5d. for 3,000 miles.

Sir WILFRID LAURIER said in view of the statement made by Mr. Samuel on the previous resolution, he reserved his judgment on the present proposal.

Sir J. WARD had the following resolution on the paper :—

"That, in order to secure a measure of unity in the cable and telegraph services within the Empire, the scheme of telegraph cables be extended by the laying of a State-owned cable between England and Canada, and that the powers of the Pacific Cable Board be extended to enable the Board to lay and control such cable."
